An unsuccessful New Jersey bill<sup>42</sup> proposed that in the distribution of the assets of an insolvent decedent the claims of physicians and nurses for services rendered during the last illness should be on a par with judgments entered against the decedent in his lifetime, funeral expenses and hospital bills and should have precedence over all other claims The Virginia house killed a bill<sup>43</sup> which proposed that the proceeds of a judgment based on a wrongful death should be paid to the personal representative of the decedent and after the payment of the costs of suit and reasonable attorney's fees, there should be paid the charges of hospitals, physicians and nurses incurred during the last illness of the decedent but not to exceed \$200 in the case of a hospital and \$50 to each such physician or nurse

Proposals to assure physicians of compensation for treating certain indigent patients were killed in Massachusetts and New York The Massachusetts bill<sup>44</sup> proposed to permit any person not in an institution and receiving public support who is in need of the services of the physician to employ, at the expense of the appropriate town, any physician who is registered for the purpose with the department of civil service A New York bill<sup>45</sup> proposed to permit any physician licensed to practice for five or more years to register with the state commissioner of health or the commissioner of health of the city of New York and thereafter be paid an annual compensation for treating such indigent persons as might be referred to him by the political subdivision in which he resides or maintains his office The bill proposed to permit any municipality to make available not exceeding \$750 per annum for each physician such municipal corporation desired to have appointed to furnish professional services to indigent persons

**PRIVILEGED COMMUNICATIONS**—Two bills were killed in Kentucky<sup>46</sup> which proposed that a physician should not be required to testify concerning a communication made to him in his professional character, by his patient, or his advice thereon, without the patient's consent An unsuccessful attempt was made in Mississippi<sup>47</sup> so to amend the law making communications made to a physician by a patient privileged as to provide that the law should not apply to criminal causes or to civil causes in which it was claimed that the patient's condition was caused by the negligence of any person and where that condition was put in issue

Another unsuccessful Mississippi bill<sup>48</sup> proposed to declare void a waiver of the privileged communications statute contained in any insurance policy

**EXPERT WITNESSES**—Two bills were killed in New York<sup>49</sup> which proposed that if in a criminal action issues arose on which the court deemed expert evidence desirable it might appoint one or more experts not exceeding three on each issue to testify at the trial Such experts were to be subject to cross examination and the fact that they were appointed

by the court should be made known to the jury. Any party to the proceeding was to be privileged to call also other expert witnesses but the court was to be authorized to impose reasonable limitations on the number of witnesses so called.<sup>50</sup>

**VENEREAL PROPRIETARIES**—A new Kentucky law prohibits the retail sale or distribution of appliances, drugs or medicinal preparations intended or having special utility for the prevention of venereal diseases, except by licentiates of the state board of pharmacy and licentiates of the board of medical examiners regularly licensed to practice medicine.<sup>51</sup>

A similar bill failed of enactment in Mississippi.

**MISCELLANEOUS**—A bill proposing to prohibit the display of the insignia of a physician on a motor vehicle except on the motor vehicle of a licensed physician failed of enactment in Massachusetts.<sup>52</sup>

The Massachusetts legislature also killed a bill<sup>53</sup> to require any chartered hospital in the commonwealth to accept any patient on the request of a licensed physician. An attempt to make exempt from seizure under execution or attachment the instruments of surgeons and dentists used in their profession, not exceeding one thousand dollars in value, was rejected in Mississippi.<sup>54</sup>

### B. Duties and Liabilities

**TREATMENT OF PREGNANT WOMEN**—Laws were enacted in New Jersey,<sup>55</sup> New York and Rhode Island<sup>56</sup> to require a physician attending a pregnant woman to take a sample of her blood and to make or cause to be made a standardologic test for syphilis.

**REPORTS OF DEATHS, DISEASES AND DEFECTS**—A new Louisiana law<sup>57</sup> requires a physician having first knowledge of the death of any person who has died suddenly, accidentally, violently or as a result of any suspicious circumstance, or without medical attendance within thirty-six hours of death, or from an abortion whether self induced or otherwise, to notify the coroner and the district attorney.

Bills to require a physician treating a patient for venereal disease to notify the appropriate health authorities failed of enactment in Georgia<sup>58</sup> and New Jersey.<sup>59</sup> Unsuccessful attempts were made in Massachusetts<sup>60</sup> to require a physician attending or called to attend a case of induced abortion to report the facts at once to the appropriate police authorities and to the appropriate medical examiner.

The New York legislature killed two proposals<sup>61</sup> to require every physician to give notice immediately to the appropriate health officer of every case of cancer or other malignant tumor coming to his attention.

**DESIGNATION OF SCHOOL OF PRACTICE**—An unsuccessful attempt was made in Rhode Island<sup>62</sup> (1) to prohibit the use of the title "doctor" or "physician" in any occupation pertaining to the public health except by practitioners of medicine licensed by the board of examiners in medicine and (2) to require all practitioners of the healing art to "display, in letters not less than half the size of those used in said person's name, the particular branch or type of the healing art practiced, on every sign, advertisement or public notice."

<sup>50</sup> These bills were practically identical with the Uniform Expert Testimony Act prepared by the National Conference of Commissioners on Uniform State Laws except that the uniform act is designed to apply to both civil and criminal proceedings whereas the New York bills were to apply only to criminal proceedings.

<sup>63</sup> N. Y. S. 1815 and A. 2241.

<sup>64</sup> R. I. S. 216.

**MISCELLANEOUS**—The legislature of Massachusetts again killed proposals,<sup>65</sup> similar to proposals before it for several successive legislative sessions, to require a physician removing any limb or organ (1) to explain to the patient the nature of the operation and the reasons that made such an operation necessary and (2) to preserve the organ so removed for six weeks unless sooner demanded by the patient. An unsuccessful Mississippi bill<sup>66</sup> proposed to make it unlawful for any physician or hospital to assign any nurse who is not a graduate or registered nurse to a special case unless the nurse receives the compensation paid by the patient for the nursing services.

### III. LEGISLATION RELATING TO ALLIED PROFESSIONS AND SUNDRY VOCATIONS

**CLINICAL LABORATORY TECHNOLOGISTS OR TECHNICIANS, CLINICAL AND BACTERIOLOGICAL LABORATORIES**—A defeated Louisiana bill<sup>67</sup> proposed to prohibit the operation of a clinical laboratory except under the immediate supervision and direction of a licensed physician or of a licensed clinical laboratory technologist. The state board of health was to be authorized to license as a clinical laboratory technologist any person who holds a degree in one or more of the fundamental sciences issued by a recognized institution and passes such examinations as the board may require. The board was also to be authorized to license as a clinical laboratory technician any person whom it found properly qualified. Such a license might be restricted to cover work in any one or more basic sciences or it might cover work in the entire field of clinical laboratory work. A technician in the bill defined as a person who under the direction of a physician or technologist "performs the technical procedure called for in a clinical laboratory," which, according to the bill, was any establishment operated for the practical application of one or more of the fundamental sciences by the use of specialized apparatus, equipment and methods for the purpose of obtaining scientific data which may be used as an aid to ascertain the presence, progress and source of diseases.

An unsuccessful attempt was made in New York<sup>68</sup> to create a board of examiners for clinical laboratory technicians and to prohibit persons from practicing or representing themselves to be licensed as clinical laboratory technicians unless licensed by the board. A "clinical laboratory technician," according to the bill, was to be any person who "performs any technical laboratory procedures, including bacteriology, immunology, serology, biochemistry, hematology, histologic technique and clinical pathology, which are used for the purpose of diagnosing, investigating or treating any disease, illness or infection."

Two bills to prohibit the operation of bacteriological laboratories except by virtue of a license or a certificate of approval from a designated agency failed in Massachusetts<sup>69</sup>. Both bills defined a bacteriological laboratory as "a place or establishment which is advertised, announced or maintained in whole or in part for the purpose of accepting for and subjecting to bacteriological study or analysis specimens of milk, water and foodstuffs or specimens of blood, sputum, urine, feces or other fluids, secretions or excretions of the body of persons ill or suspected of being ill with a disease dangerous to the public health."

**OPERATION OF AMBULANCES**—A new Louisiana law<sup>70</sup> makes it unlawful to conduct or operate an ambulance unless the ambulance is under the immediate supervision and direction of a person licensed to practice medicine and surgery or a person holding a first aid certificate. The act further provides "Nor shall any person be employed in any capacity on any 'ambulance' unless the said person is the holder of a 'first aid certificate' as herein defined." A "first aid

<sup>65</sup> Mass. H. 604 H. 605.

<sup>66</sup> Miss. H. 364.

<sup>67</sup> La. H. 186.

<sup>68</sup> N. Y. S. 1373.

<sup>69</sup> Mass. S. 361 H. 1297.

<sup>70</sup> La. Acts 1938 Act No. 234.

certificate," according to the act, refers "to any certificate issued by either the Bureau of Mines or by the American Red Cross wherein it is stated that the person to whom it is issued has successfully completed the required training and met the established standards of such organizations."

**DISPENSARIES**—The New York law prohibiting the operation of a dispensary without a license so to do was so amended this year<sup>1</sup> as expressly to exempt from the law "the state departments of health, mental hygiene, and education, or any institution subject to their jurisdiction, a local department of health or board of education."

**DENTISTRY**—Amendments to existing dental practice acts were adopted in Kentucky,<sup>2</sup> Rhode Island<sup>3</sup> and South Carolina<sup>4</sup>. Of particular interest to physicians is one of the provisions in the new Kentucky law which prohibits licensed dentists from announcing their profession to the public in any manner other than that set forth in the law. The law specifies that the professional card of a licensed dentist may contain only his name, title (such as D.D.S. or D.M.D.), address, telephone number and office hours. The law, however, permits any dentist who confines his practice to any one branch of dental practice also to specify that his practice is limited to a stated branch of dental practice and to set forth the title of that branch.

An unsuccessful attempt was made to amend the dental practice act of Georgia.

**NURSING**—A new nursing practice act was adopted in New York.<sup>5</sup> The new law prohibits the practice of nursing unless the person is licensed to do so by the department of education as either (a) a registered professional nurse or (b) a practical nurse. The law defines the practice of nursing as the performance for compensation or personal profit (1) of any professional service requiring the application of principles of nursing based on biologic, physical or social sciences, such as responsible supervision of a patient requiring skill and observation of symptoms and reactions and the accurate recording of the facts, and carrying out of treatments and medications as prescribed by a licensed physician, and the application of such nursing procedures as involve understanding of cause and effect in order to safeguard life and health of a patient and others, or (2) of such duties as are required in the physical care of a patient and in carrying out of medical orders as prescribed by a licensed physician, requiring an understanding of nursing but not requiring the professional service as outlined in 1. For an applicant to be licensed as a registered nurse he or she must submit evidence among other things of having completed an approved four year high school course and a course of study in a school of nursing registered by the department. For an applicant to be licensed as a practical nurse he or she must submit evidence of having completed at least the eighth grade or its equivalent and of having completed the course of study in a school for the training of practical nurses giving a course of not less than nine months.

An unsuccessful attempt was made to amend the nursing practice act of Massachusetts.

- 71 N.Y. Laws 1938 c. 123  
72 Ky. Laws 1938 c. 148  
73 R.I. Laws 1938 c. 258  
74 S.C. Acts 1938 Act No. 737  
75 Ca. H. 504 N. (first special session)  
76 N.Y. Laws 1938 c. 472 (Five other similar bills S. 187 S. 243 S. 526 A. 332 A. 1224 were also considered)  
77 Va. H. 1196

Unsuccessful attempts were made in two states<sup>78</sup> to grant to nurses treating persons injured through the fault of others liens on all rights of action, claims or demands accruing to the injured persons by reason of their injuries. Other proposals to give nurses a preferential position with respect to claims for services rendered are discussed under "Insuring Payment of Medical Bills."

**CHIROPODY**—A separate chiropody or podiatry practice act was enacted in Mississippi.<sup>79</sup> The new law authorizes the state board of health to examine persons to practice chiropody or podiatry, which is defined in the law as "the diagnosis and medical, mechanical, electrical and surgical treatment of the ailments of the human foot, such as corns, calluses, warts, arches, ingrowing and abnormal nails, bunions, and similar conditions." Such practitioners are to be permitted to use "such mechanical appliances as may be deemed necessary for the relief or cure of such ailments of the feet, except amputation of the foot or toes, or the use of anesthetics other than local anesthetics related to the part affected used to prevent operative or mechanical pain." Diseases and conditions of the feet produced by kidney, heart or other systemic diseases are not to be treated by persons licensed to practice chiropody or podiatry except under the direction and supervision of a regularly licensed physician.

The chiropody practice act of Rhode Island was so amended this year<sup>80</sup> as to make it illegal and a ground for revocation of a license for a chiropodist to sell or give away any substance or compound containing alcohol or narcotic drugs "for other than legal purposes." The amendment also lays down somewhat rigid restrictions on the advertising activities of licensed chiropodists.

An unsuccessful attempt was made in New Jersey<sup>81</sup> to enact a separate chiropody practice act and to create an independent board of chiropody examiners.

**PHARMACY**—Amendments to the Kentucky pharmacy practice act adopted this year<sup>82</sup> are not of sufficient interest to the medical profession to warrant detailed discussion.

Proposals to amend existing pharmacy practice acts in Mississippi<sup>83</sup> and New York<sup>84</sup> were killed. A proposal<sup>85</sup> failed so to amend the New Jersey pharmacy practice act as, in effect, to permit the vending of patent or proprietary medicines in sealed packages and the vending of commonly used household or domestic remedies in original unopened packages by persons other than registered pharmacists.

**OPTOMETRY**—Amendments to existing optometry practice acts were adopted in Kentucky,<sup>86</sup> Massachusetts<sup>87</sup> and Virginia<sup>88</sup>. The new Kentucky law defines optometry as "the examination of the human eye without the use of drugs, medicines or surgery, to ascertain the presence or defect of abnormal conditions which can be corrected by the use of lenses, prism, or ocular exercises and their adaptation for the aid thereof." The new law also prohibits false misleading or bait advertising by optometrists and authorizes the issuance of an injunction to restrain the violation of any provision of the law relating to optometry. The

new Massachusetts law strikes out provisions in the prior law which seemed to permit the corporate practice of optometry. The new Virginia law, among other things, imposes certain restrictions on advertising by optometrists.

Attempts to amend the optometry practice act of two other states failed.<sup>89</sup>

An unsuccessful attempt was made in New York<sup>90</sup> to create a state board of dispensing opticians and to regulate the practice of ophthalmic dispensing which, according to the bill,

<sup>89</sup> N. Y. S. 1398 A 1744 R. I. S. 144  
<sup>90</sup> N. Y. A. 711

consisted in "the filling or dispensing to the ultimate consumer of ocular prescriptions involving lenses, spectacles, eyeglasses, optical devices or any ophthalmic appliances except drugs and medicines, as prescribed by physicians and by optometrists, and intended to be used for eyewear or for the aid, correction, relief or treatment of the external features of the face and head of said consumer for the proper designing and fitting required by such prescriptions." An unsuccessful attempt was made in New Jersey<sup>91</sup> to authorize every board of education to employ an optometrist to examine and inspect the eyes of school children.

(To be continued)

<sup>91</sup> N. J. S. 262

## MEDICAL LEGISLATION

### MEDICAL BILLS IN CONGRESS

*Change in Status*—H. Res. 60 has been agreed to, authorizing the House Select Committee on Government Organization to continue its work begun under authority of a resolution passed by the Seventy-Fifth Congress.

*Bills Introduced*—S. 795, introduced by Senator Pepper, Florida, proposes to authorize an appropriation of \$11,580,000 annually, beginning with the fiscal year ending June 30, 1940, to assist each state to establish, extend and improve services for educating physically handicapped children. The term "physically handicapped" is defined in the bill as including "all children who are crippled, blind, partially seeing, deaf, hard of hearing, defective in speech, cardiopathic, tuberculous, or otherwise physically handicapped, and who for their education require an expenditure of money in excess of the cost of educating physically normal children." H. R. 2725, introduced (by request) by Representative Rankin, Mississippi, proposes to provide benefits to certain veterans and to the dependents of such veterans. Among other things, the bill provides that any person who served in the military or naval forces of the United States during a recognized campaign or expedition, and who was honorably separated from such service, shall be granted hospitalization and domiciliary care by the Veterans' Administration subject to the same restrictions and limitations as are now applicable to World War veterans. H. R. 3043, introduced by Representative Schwert, New York, proposes to provide that on and after the enactment of the bill any World War veteran suffering from paralysis, paresis or blindness, or who is helpless or bedridden as the result of any disability, or who is otherwise totally disabled may be awarded compensation under the laws and interpretations governing this class of cases prior to the enactment of the Economy Act of March 20, 1933. H. R. 3220, introduced (by request) by Representative May, Kentucky, proposes to extend the benefits of the United States Employees' Compensation Act to members of the Officers' Reserve Corps and of the Enlisted Reserve Corps of the Army who are physically injured in line of duty while performing active duty or engaged in authorized training. H. R. 3533, introduced by Representative Sheppard, California, proposes to authorize an appropriation of \$500,000 to construct a 200 bed hospital in the Mojave Desert of San Bernardino or Riverside County, Calif., to provide hospital, domiciliary care and outpatient dispensary facilities to care for "the increasing numbers of disabled veterans of all wars suffering from disease of the chest and to enable the Veterans' Administration to care for its beneficiaries in Veterans' Administration institutions." H. R. 3537, introduced by Representative McReynolds, Tennessee, proposes to extend the facilities of the United States Public Health Service to active officers of the Foreign Service of the United States.

### STATE MEDICAL LEGISLATION

#### California

*Bill Passed*—S. 205 passed the Senate January 23 and the House January 24, proposing to supplement the Business and Professions Code by adding a cosmetology practice act. The bill proposes to permit cosmetologists, among other things, to remove superfluous hair from the body of any person by the

use of electrolysis, depilatories, tweezers, chemicals, preparations or devices or appliances of any kind, except by the use of light waves.

*Bills Introduced*—A. 714 proposes that all persons must, before obtaining a marriage license, present to the county clerk a physician's certificate that each applicant has been given such examination, including a standard serologic test, as may be necessary for the discovery of syphilis, made on any day not more than twenty days prior to the date of application, which certificate also must contain an opinion of the physician that the parties are not infected with syphilis or, if so infected, are not in any stage of that disease whereby it may become communicable. A. 831 proposes to require a physician attending a pregnant woman to take or cause to be taken a sample of her blood at the time of the first examination and to submit the sample to an approved laboratory for a standard serologic test for syphilis. The bill also proposes that every other person permitted by law to attend pregnant women but not permitted to take blood tests cause a sample of the blood of such pregnant woman to be taken by a duly licensed physician and submitted to a laboratory for the test referred to above. A. 1246 to supplement the Code of Civil Procedure, proposes that, whenever it shall be relevant to the prosecution or defense of an action, the court may direct any party to the action and the child of any such party and the person involved in the controversy to submit to one or more blood grouping tests, the results thereof to be receivable in evidence only where definite exclusion is established.

#### Connecticut

*Bills Introduced*—S. 167 proposes to enact a uniform food, drug and cosmetic act and to forbid the sale or distribution of adulterated or misbranded foods, drugs, cosmetics and therapeutic devices. H. 180, to amend the workmen's compensation act, proposes to permit an injured employee to select the physician whom he desires to treat him for his industrial injury and to make the employer liable for such medical and surgical and hospital service as that physician deems reasonable or necessary. H. 297 proposes to prohibit the sale or distribution of dangerous caustic and corrosive substances unless in containers bearing a conspicuous, easily legible label or sticker, containing (a) the name of the article, (b) the name and place of business of the manufacturer, packer, seller or distributor, (c) the word "POISON" in letters of not less than 24 point size, and (d) directions for treating a case of accidental personal injury.

#### Georgia

*Bills Introduced*—S. 28 proposes to require all applicants for licenses to practice any form of the healing art as a condition precedent to examination and licensure by the respective professional boards, to pass examinations in anatomy, physiology, chemistry, bacteriology and pathology to be given by a board of examiners in the basic sciences. No member of the board can be actively engaged in the practice of the healing art or any branch thereof. S. 29 proposes to license to practice medicine to citizens of the United States. S. 42 and H. 222 propose, as a condition precedent to the issuance of a license to marry, that both parties to the proposed marriage present certificates signed by licensed physicians that

they have examined both parties to the proposed marriage and find no clinical evidence of syphilis, that they have performed serologic tests for syphilis as approved by the United States Public Health Service, and that in their opinion the parties are not infected with syphilis as to be now communicable or likely to be communicable. H 227, to amend the workmen's compensation act, proposes to permit injured employees to select, at the expense of the employer and his insurance carrier, any reputable physician or surgeon in good standing to treat their industrial injuries.

#### Indiana

*Bills Introduced*—S 93 proposes to prohibit the employment of persons in public schools unless prior to the beginning of each school year they present certificates signed by licensed physicians that they are free from any transmissible or communicable disease. H 21 proposes to require every physician attending a pregnant woman to take or cause to be taken a sample of her blood "at the time of diagnosis and to submit such sample to an approved laboratory for a standard serologic test for syphilis. This bill was reported favorably to the house January 17.

*Bill Passed*—H 74 passed the house January 27, proposing that any legal resident of the state over 16 suffering from a condition or malady or deformity susceptible of improvement, cure or benefit by medical or surgical treatment or hospital care or by special study and diagnosis may be admitted on the commitment of any judge to any hospital operated by the trustees of Indiana University.

#### Iowa

*Bill Introduced*—S 27 proposes as a condition precedent to the issuance of a license to marry, that each party to a proposed marriage present a physician's certificate that he or she is "either free from syphilis or not in a stage whereby it may become communicable as nearly as can be determined by a thorough physical examination and such standard microscopic and serological tests as are necessary for the discovery of syphilis."

#### Maryland

*Bills Introduced*—S 10 proposes to repeal the Maryland laws relating to coroners and to provide for the creation of a new executive and administrative department to be known as the Department of Post Mortem Examiners. The head of the department is to be a commission consisting of the professors of pathology of the University of Maryland and of Johns Hopkins University, the director of health of the state, the commissioner of health of Baltimore City and the superintendent of Maryland state police. This commission is to be authorized to appoint a chief medical examiner and two assistant medical examiners, all of whom must be licensed doctors of medicine and have had at least two years postgraduate training in pathology. The commission is also to be authorized to appoint a deputy medical examiner, who also must be a licensed physician, for each county of the state. Whenever any person dies as a result of violence, by suicide or casualty, suddenly when in apparent health, when unattended by a physician or in any suspicious or unusual manner it is to be the duty of the police authorities immediately to notify the chief medical examiner or a deputy medical examiner. The medical examiner is then to go to the dead body and take charge of it, investigating the essential facts concerning the circumstances of the death. If in the opinion of the medical examiner an autopsy is necessary it shall be performed by the chief medical examiner, an assistant medical examiner or by such competent pathologists as may be authorized by the chief medical examiner. H 15 and S 12 propose to create a department of professional and vocational licensing to perform all the clerical, secretarial and financial duties of existing boards and commissions examining and licensing persons to practice stated professions and vocations, including the board of dental examiners, the board of commissioners of pharmacy, the boards of examiners of nurses, optometry, osteopathy, chiropody and chiropractic but apparently not including the two boards of medical examiners.

#### Massachusetts

*Bill Introduced*—H 852 authorizes the department of public health to license hospitals, convalescent homes, nursing homes, rent homes and sanatoriums. Presumably if the bill is enacted it will be unlawful to operate any of the institutions referred to unless licensed by the department. H 1220 proposes a tax of 2 per cent on gross income over \$1,000 accruing from any gainful pursuit, which is so defined as to include any occupation, profession, means of livelihood or support, trade or enterprise. H 1265 proposes to direct the state department of public health to furnish not less than two oxygen tents to each hospital in cities of more than 30,000 population. H 1277 proposes to permit persons receiving public support to select, at the expense of the appropriate town, such physicians as they desire to render necessary medical services.

#### Michigan

*Bill Introduced*—S 59 proposes to repeal the uniform narcotic drug act enacted in 1937.

#### Minnesota

*Bill Introduced*—H 234, to amend the workmen's compensation act, proposes to permit an employer to furnish chiropractic treatment to an injured employee.

#### Missouri

*Bills Introduced*—H 39 proposes, as a condition precedent to the issuance of a license to marry, that both parties to the proposed marriage present certificates signed either by licensed physicians or by directors of laboratories approved by the department of health that both parties are free from all venereal disease. Apparently such a certificate cannot be executed until a blood test has been made on the applicant's "venous blood serum" not more than fifteen days before the application in a laboratory acceptable to the state department of health. A license to marry may issue even though a blood test was positive if a licensed physician will certify that in his opinion any venereal disease, if present, is not in a communicable stage. S 5 proposes, as a condition precedent to the issuance of a license to marry, that both parties to the proposed marriage present certificates from licensed physicians that they are free from all venereal diseases as nearly as can be determined by a thorough physical examination. These certificates must be accompanied by "laboratory reports of microscopical examination for the gonococcus for gonorrhea, and the blood Wassermann test or the Kahn test for syphilis, or such other serological tests as shall be approved by the State Board of Health." S 22 proposes to grant to governmental hospitals and hospitals supported in whole or in part by charity treating persons injured through the negligence of others liens on all claims, demand, rights of action, judgments or settlements accruing to the injured persons because of their injuries.

#### Nevada

*Bill Introduced*—A 20 proposes an entirely new pharmacy practice act, proposing to prohibit the sale or distribution, except by licentiates of the State Board of Pharmacy, of drugs and devices, appliances and the medicinal agents used in the prevention of venereal diseases. The bill also proposes to authorize the Board of Pharmacy to adopt and promulgate such standards relating to and governing venereal prophylactics as it deems necessary. The bill specifically provides that Physicians are exempted from the provisions of this act when disposition [presumably of drugs and venereal prophylactics] is made in the regular practice of their profession and to their patients in the manner specified for a license.

#### New Jersey

*Bill Introduced*—A 61 proposes that whenever it is relevant in a proceeding involving parentage of a child the trial court may direct the mother, the child and the defendant to submit to one or more blood grouping tests to determine whether or not the defendant can be excluded from the probability of being the father of the child. Testimony with respect to the results of the tests however is to be receivable in evidence only where definite exclusion of parentage of the defendant is indicated. The bill also proposes to authorize such test whenever it shall be relevant in a civil action to determine the parentage or the identity of any child or other person.

**New Mexico**

*Bill Introduced*—H 58 proposes 'That the making and performing of contracts by Hospitals or Sanatoriums for the furnishing of hospital care, with or without medical or surgical attention, shall not be classified or considered as the writing of insurance or the doing of insurance business, and no law of the State of New Mexico pertaining to insurance shall affect any such contract'

*Bill Passed*—S 8, which was introduced on January 16, passed the senate on January 19, proposing to enact a separate naturopathic practice act and to create a board of naturopathic examiners to examine and license applicants for licenses to practice naturopathy. A license to practice naturopathy under the terms of the bill is to permit the holder thereof 'to diagnose and treat human beings using natural and drugless methods without the use of major surgery, as taught in standard and chartered Naturopathic colleges, schools or universities wherein the curriculum of study includes instructions in the following subjects: Anatomy, Physiology, Pathology, Hygiene and Sanitation, Chemistry, Diagnosis, Symptomatology, Non-Surgical Gynecology, Mid-Wifery, Jurisprudence, First Aid, Physical Culture and Manipulation, Food Sciences and Fasting, Endocrinology, Electrotherapy, Autotherapy, Biochemistry, Phytotherapy, Hydrotherapy, Mechanotherapy, Massage, Psychology and Mental Science, Sun and Air Bathing, and the Philosophy, Theory, and Practice of Naturopathic Therapeutics'

**New York**

*Bills Introduced*—S 337 and A 413 propose to grant to a physician treating a person injured through the negligence of another a lien on all claims, rights of action, judgments or settlements accruing to the injured person by reason of his injuries

**North Carolina**

*Bill Introduced*—H 59, to amend the pharmacy practice act, proposes that "all proprietary drugs, remedies, patented cures, powders and devices containing [opium, acetamide, and cannabis] manufactured and/or sold in this state shall be marked poison in red ink on the container in which they are manufactured and/or offered for sale to the public"

**Rhode Island**

*Bill Introduced*—H 583 proposes to authorize the formation of nonprofit hospital service plan corporations to render, through contracting hospitals, hospital care to subscribers to such hospital service plans

**South Carolina**

*Bill Passed*—H 16 passed the house and senate, proposing to authorize the Charleston County Public Welfare Board to make application to any appropriate agency of the United States for a grant for constructing and equipping a county hospital, nurses' home and such other buildings as are necessary for the operation of a county hospital

**South Dakota**

*Bills Introduced*—H 24, to supplement the osteopathic practice act, proposes to authorize the board of osteopathic examiners under such regulations as it may prescribe to license osteopaths to practice surgery in all its branches. H 47 proposes, in effect, to permit all relief clients in need of medical services to select "any regularly licensed physician or practitioner of the healing arts of his choice." This bill was reported favorably to the house January 25. S 25 proposes that all persons rendering personal service of every kind and description shall have a lien on all the property, both real and personal, of the person or persons employing them and that this lien be subject and inferior only to mortgages and conditional sale contracts properly filed on or before the time when said personal services are engaged

**Tennessee**

*Bill Introduced*—H 392 proposes to enact a separate naturopathic practice act and to create a board of naturopathic examiners to examine and license persons to practice naturopathy. The bill proposes that naturopathy "shall comprehend, embrace and be composed of the following acts, practices and usages

Diagnosis and practice of Physiological and mechanical sciences, and such as mechanotherapy, articular manipulation, corrective and orthopedic gymnastics, neurotherapy, psychotherapy, hydrotherapy and mineral baths, electrotherapy, phototherapy and dietetics which shall include the use of foods of such biochemical tissue-building products and cell salts as are found in the normal body. Provided, however, that nothing in this section shall be held or construed to authorize any Naturopathic Physician licensed hereunder to practice Materia Medica, Major Surgery, or Radium Therapy, nor shall the provisions of this Act in any manner apply to or affect the Practices of Osteopathy, Chiropractic, Christian Science, or any other therapy authorized or provided for by law for the cure and prevention of diseases except that no privilege recorded other Drugless Physicians this State shall be denied to Naturopathic Physicians"

**Texas**

*Bills Introduced*—H 223 proposes to enact a new state sanitary health code, vesting in the State Board of Health and the state and local health officers certain powers and duties with respect to the control and prevention of disease, the reporting and management of communicable diseases, the quarantine of carriers, and matters relating to sanitation in general. H 2 proposes to enact a new law regulating the sale and distribution of foods, drugs, cosmetics and therapeutic devices. H 22 proposes extensive amendments to the Uniform Narcotic Drug Act adopted in 1937. Among other things the bill proposes that while a physician or dentist may prescribe, administer and dispense narcotic drugs in good faith and in the course of his professional practice or he may cause them to be administered by a nurse or intern under his direction, he may do so only after physical examination of the person for whom the drugs are intended, the examination to be made at the time the prescription is issued or at the time the drugs are administered, dispensed, given away or delivered by the physician or dentist. The bill also specifically proposes to make it unlawful for any physician, dentist or veterinarian to prescribe, dispense or administer to himself as a habitual user or merely to satisfy his own craving

**Utah**

*Bills Introduced*—S 20 proposes to enact a new law prohibiting the manufacture, advertising, sale, delivery for sale, or offering for sale of adulterated and misbranded food drugs, therapeutic devices and cosmetics. This bill was reported favorably to the senate January 23. S 86 proposes to impose an excise tax of 15 per cent of the wholesale price on the first sale within the state of all proprietary and "patent medicines"

**Washington**

*Bills Introduced*—S 41 proposes to make it unlawful for any person operating a bathhouse, massage parlor or similar establishment by himself or agent to furnish any bath, massage or other treatment or to attempt to treat any disease, injury or condition of health, unless the person so doing is licensed to practice one of the healing arts authorized by the laws of the state. S 83, to amend the workmen's compensation act, proposes to permit an injured employee to select any licensed practitioner of the healing art to attend him. H 60 proposes to prohibit the sale or distribution of articles or drugs designed, intended or which may have special utility for the prevention and/or treatment of venereal diseases except by virtue of a license issued by the state board of pharmacy. A physician and surgeon, however, may sell or distribute such articles and drugs without obtaining the licenses referred to

**West Virginia**

*Bills Introduced*—S 16 proposes that the provisions of the sales tax law shall not apply to "sales of medicine whose use is prescribed or directed by a duly qualified physician." H 117 and S 63 propose, as a condition precedent to the issue of a license to marry, that both parties present physicians' certificates stating that they have been given such examination, including a standard serologic test, as may be necessary for the discovery of syphilis and that in the opinion of the physicians both parties are either not infected with syphilis or, if so infected, are not in a stage of the disease which is or may later become communicable

### ARKANSAS

**WPA Hospital Projects in Arkansas**—More than \$1,000,000 has been expended by the WPA on publicly owned hospitals and sanatoriums in the state since the work relief program was inaugurated in Arkansas in 1935, according to a recent report. About \$500,000 has been used toward relieving conditions at state hospitals and for facilities to treat tuberculous patients. Improvements at the state hospital unit in Little Rock accounted for \$274,300 of the total expenditure, not including \$159,000 previously spent by the Civil Works Administration and the federal emergency relief administration. The largest expenditure toward improving facilities for state operated tuberculosis sanatoriums was the donation of the transient camp at Fort Smith as an auxiliary unit of the state tuberculosis sanatorium at Booneville. A total of \$50,000 was spent by the emergency relief administration for construction of the camp, while the WPA spent \$145,000 in remodeling the buildings for hospital use. Work has been started on a \$250,000 unit at Alexander to increase the capacity for the McRae Tuberculosis Sanatorium for Negroes from thirty-one to 150 beds, the state is sponsoring the project. Other expenditures include the construction of 100 portable cottages at Camden, Jonesboro, Searcy, Blytheville, Morrilton, Pine Bluff, Little Rock, Batesville and Monticello for the treatment of patients who have been discharged from the state institutions but who are not sufficiently recovered to receive employment. An additional \$299,000 has been spent for improvements on government operated hospitals. The Veterans' Facility, Fort Roots sponsored projects totaling \$170,000, while a project totaling \$38,000 was begun at the Army and Navy General Hospital, Hot Springs National Park. Other hospitals aided under the program were Henderson State Teachers Infirmary, Arkadelphia \$4,000, new hospital for the State School for the Blind, \$18,500, School for the Deaf Infirmary, \$1,300, Julia Chester Hospital, Hope, \$2,000, Morrilton nurses' home \$5,700, Helena City Hospital, \$82,700, City Hospital, Little Rock \$6,300, City Hospital Conway, \$14,000, Jefferson County Hospital, Pine Bluff \$27,700, and Luvora indigents' home, \$36,500.

### CALIFORNIA

**Outbreak of Septic Sore Throat**—Twenty-four cases of epidemic septic sore throat with two deaths were reported in a southern county, according to *California and Western Medicine*. All the patients were on the same raw milk dairy route. The investigation disclosed that one person with the disease had worked in the dairy a few days before the onset of symptoms in consumers of the milk.

**Course in Ophthalmology and Otolaryngology**—The eighth annual midwinter course in ophthalmology and otolaryngology conducted by the Research Study Club of Los Angeles, January 16-27, included the following instructors:

Dr. Gosta Dohlman professor of otolaryngology Lund University Lund Sweden  
Dr. Edward Jackson professor of ophthalmology emeritus University of Colorado School of Medicine Denver  
Dr. John F. Barnhill emeritus professor of head surgery Indiana University School of Medicine Indianapolis  
Dr. William L. Benedict chief of the department and professor of ophthalmology of the Mayo Foundation Rochester Minn  
Dr. Phillips Thygeson assistant professor of ophthalmology Columbia University College of Physicians and Surgeons New York  
Dr. George N. Horsford San Francisco  
Dr. Augustus Pohlman formerly professor of anatomy Creighton University School of Medicine Omaha  
Dr. Simon H. Jesberg associate clinical professor of surgery (otology, rhinology and laryngology) University of Southern California School of Medicine Los Angeles  
Dr. Louis K. Guggenheim assistant professor of clinical otolaryngology Washington University School of Medicine St. Louis

**Officers Chosen for State Insurance Plan**—Dr. Ray Lyman Wilbur, president of Stanford University and past president, American Medical Association January 29 was elected president of the board of trustees of the California Physicians' Service, the recently adopted statewide health insurance system to work through the California Medical Association. Dr. Morton R. Gibbons Sr. San Francisco was appointed medical director of the system. At this meeting

the board of trustees appointed a committee to visit Seattle and study the King County plan," which provides for medical care for about 35,000 workers in and around Seattle and which resembles the California project, it was stated. With the report of this committee plus other information now being gathered, the trustees will be enabled to decide on the type of service to be offered to the state's population and its cost. Other officers named at the meeting include Drs. Clarence Kelly Canelo, San Jose, and Lowell S. Goin, Los Angeles, vice presidents, Alson R. Kilgore, San Francisco, secretary-treasurer, and Thomas Henshaw Kelly, San Francisco, assistant secretary-treasurer.

### FLORIDA

**Naturopaths Denied Right to Use Narcotics**—Florida naturopaths are not entitled to registration under the Harrison Narcotic Act because they are not authorized to use narcotics by the law under which they are licensed, according to a recent decision of the United States District Court, Southern District, Florida, in two cases consolidated for hearing, *Perry v. Larson*, Collector of Internal Revenue, and *Detwiler* against the same defendant. The court pointed out that whether or not a person is entitled to registration under the Harrison Narcotic Act is not determinable by that act itself but by the law of the state where the person resides. The naturopathic act of Florida authorizes naturopaths to employ, among other things, phytotherapy, which the naturopaths argued embraces all botanical preparations and their compounds, from which they concluded that they are authorized to prescribe and administer morphine, and other narcotics of botanical origin. But, the court said, after authorizing the employment of phytotherapy, the act specifically denies to naturopaths the right to practice *materia medica*, or the right to engage in that branch of medical science which deals with drugs, their sources, preparations and uses. The situation was not altered, the court thought, by the fact that narcotics are used "merely as a palliative [sic] to overcome pain, rather than as a specific treatment for an ailment." Although the Florida naturopathic act refers generally to phytotherapy as embraced within the practice of naturopathy, the course of study prescribed for naturopaths by the act does not include a study of botanical compounds or extracts generally, nor of narcotics. This omission seemed to the court to be significant. A verbatim copy of the decision of the court is printed in the January, 1939, issue of the *Journal of the Florida Medical Association* pages 345-346.

### GEORGIA

**Personal**—Dr. Horace G. Huey, Homerville, has been reappointed a member of the state board of medical examiners. —Dr. Clair A. Henderson formerly of Ashburn, has been elected commissioner of health for Terrell County with headquarters in Dawson.

**Graduate Assembly**—The second Atlanta Graduate Medical Assembly was held in Atlanta January 16-19, with the following participants:

Dr. Walter C. Alvarez Rochester Minn. Useful Hints in the Diagnosis of Digestive Diseases  
Dr. Isaac A. Bigger Richmond Va. Suppurative Pericarditis  
Dr. Paul D. White Boston Heart Attacks  
Dr. Merrill C. Sosman Boston Diagnosis and Treatment of Pituitary Tumors  
Dr. Herman L. Kretschmer Chicago Technique and Results in Transurethral Prostatic Resection  
Dr. Waltman Walters Rochester Minn. Lesions of the Gallbladder and Biliary Tract  
Dr. Louis Hamman Baltimore Bronchial Stenosis  
Dr. Emil Novak Baltimore Gynecologic Endocrinology for the General Practitioner  
Dr. Fred Wise New York The Deeper Seated Affections Caused by the Ringworm Fungi  
Dr. Hugo Roesler Philadelphia Diagnosis of Heart Disease Without Instrumental Aid  
Dr. Edward A. Schumann Philadelphia The Cesarean Section  
Dr. Horton R. Caspary Nashville Tenn. Children's Place in the Tuberculosis Program

### IDAHO

**Society News**—Dr. Richard P. Howard Pocatello discussed Cardiac Irregularities before the Pocatello Medical Society at its meeting at the Rannock Hotel Pocatello January 5.—Dr. Clarence M. Hyland Los Angeles addressed a recent meeting of the Boise Physicians Club on "Use of Convalescent Serum in Treatment of Acute Contagious Diseases."

**County Society Initiates Action for Health Program**—A committee with Dr. Arthur C. Jones in charge has made a vigorous appeal for a revamped and modernized health program for Boise and Ada County, according to *Northwest*

**Medicine** The establishment of a county health unit under the direction of a trained public health administrator and a legal, medical and dental clinic was recommended. Improvement in the care of the tuberculous and better care for indigents were urged. The committee also asked for the cooperation of county commissioners, dentists, lawyers, the state department of public assistance and the state health department.

### ILLINOIS

**Respirators Available to Physicians**—Seven Drinker respirators were turned over to the managing officers of seven state hospitals at appropriate ceremonies in Springfield December 28. The respirators were to be installed at Anna, Alton, Dixon, Elgin, Jacksonville, Kankakee and Peoria and will be available on short notice, so far as practicable, to physicians on request.

**Association for Recovered Mental Patients**—Patterned after the recently organized Association of the Former Patients of the Psychiatric Institute of the University of Illinois and the state department of public welfare associations are being formed at the state hospitals of Chicago, Moline, Kankakee, Alton, Anna and Jacksonville. A similar organization was formed by the recovered patients of the Peoria State Hospital. The initial group publishes its own journal, having as its objective the eradication of the stigma attached to mental patients. Meetings have been held and efforts are under way to bring about legislative action to rid the mental patient and his family of the disgrace of the court record. With a view to introducing legislation to change the existing commitment laws, the Illinois Psychiatric Society has appointed a committee of five to study the situation. Members of the committee are Drs. Francis J. Gerty, David Slight, Thomas M. French, Clarence A. Neumann and Abraham A. Low, who is president of the Association of Former Patients.

### Chicago

**Lectures on Psychoanalysis**—The Institute for Psychoanalysis began a series of lectures at the Chicago Women's Club January 24. The theme of the lectures is the recent progress in psychoanalysis in relation to the following subjects:

Dr. Franz G. Alexander, January 24, Medicine  
Dr. Karl A. Menninger, Topeka, Kan., January 31, Psychiatry  
Dr. Gregory Zilboorg, New York, February 7, History  
Dr. George J. Mohr, February 14, Problems of Children's Behavior  
Dr. Leon J. Saul, February 21, Social Sciences  
Dr. Alexander, February 28, Criminology  
Dr. Helen Vincent McLean, March 7, Literature  
Dr. Thomas M. French, March 14, Social Work

**Dr. Stone Will Lecture on Cancer**—Dr. Robert S. Stone, professor of radiology, University of California Medical School, San Francisco, will deliver the first two lectures of the Educational Association on Cancer Lectureship Fund, February 15-16, in room P 117, Billings Hospital. His subjects will be "The Position of Supervoltage in the Treatment of Cancer with X-Rays" and "Theoretical and Practical Considerations Concerning Fast Neutrons in the Treatment of Cancer." The lectureship is financed by the Education Association on Cancer through the committee on cancer of the University of Chicago. The committee was established in August 1938 and represents various departments in the university.

### MICHIGAN

**Applications for Medical Aid Increase**—A total of 11,574 applications for medical aid are recorded in the annual report on the medical aid department of the Wayne County Probate Court for the fiscal year Dec. 1, 1937, to Nov. 30, 1938. This total compares with 7,257 as of two years previously, according to *Detroit Medical News*. Dr. Paul F. McQuiggan is medical coordinator of the probate court of the county.

**Ballin Memorial Lectures**—Infection will be the theme of the sixth series in the Dr. Max Ballin Memorial Lectures to open at the Detroit Institute of Art, February 15, under the auspices of the North End Clinic. Dr. Plinn F. Morse, Detroit, will deliver the first lecture on "The Diagnosis of Fevers of Unexplained Origin." Other speakers will be:

Dr. Lewis T. Pollock, Chicago, February 22, Infections of the Central Nervous System  
Dr. George A. Myers, Detroit, March 1, Recent Advances in the Mode of Action and Uses of Sulfanilamide  
Dr. Daniel N. Silverman, New Orleans, March 8, The Dysenteries

**Regional Conferences of Health Department**—The Michigan State Department of Health is sponsoring regional conferences of local health departments in cooperation with the full-time health officers to correlate the activities and

improve the services. The meetings are to be held every two months in each of the districts which have been organized on a regional basis, the state medical journal reports. The first conference was held December 7 at Big Rapids with Dr. Max C. Igloe, director of the Mecosta-Osceola health department, as host. Included in this unit are Mecosta, Osceola, Clare, Gladwin, Arenac, Isabella, Midland and Bay counties. The Northern Michigan conference was held December 14.

**Society News**—The Northern Michigan Medical Society was addressed in Petoskey, January 12, by Dr. Henry K. Rancom, Ann Arbor, on "Surgery of the Stomach and Duodenum."—Dr. Sumner L. S. Koch, Chicago, addressed the Genesee County Medical Society, January 25, on "Infections of the Hands."—Dr. William E. Gallie, Toronto, Ont., discussed "Fracture of the Neck of the Femur" before the Wayne County Medical Society, Detroit, January 23, under the auspices of the Michigan Orthopedic Society.—At a meeting of the Detroit Pediatric Society, February 1, Dr. Walter M. Boothby, Rochester, Minn., spoke on oxygen therapy.—Dr. William W. Thoms, Kuwait, Arabia, addressed the Washtenaw County Medical Society, Ann Arbor, January 10, on "Medical Experiences in Arabia."

### NEBRASKA

**Society News**—Dr. Elliott P. Joslin, Boston, addressed the Omaha-Douglas County Medical Society, January 10, on "Treatment of the Diabetic Today."—A symposium on pneumonia was presented before the Five County (Cedar, Wayne, Dixon, Dakota and Thurston counties) Medical Society recently at Laurel by Drs. Winfred R. Blume, South Sioux City, and Allen C. Starr, and Leo L. Wilson, Sioux City, Iowa, Fred G. Dewey, Coleridge, Jerry C. Kildebeck, Emerson, Walter Benthack, Wayne.—Speakers at a meeting of the Madison Six County Medical Society, Norfolk, recently were Drs. Earl E. Pate, on "Some Psychological Aspects in the Treatment of Venereal Disease," Anthony E. Colitti, "Metrazol in the Treatment of Some Psychoses," Charles G. Ingham, "Factors Governing the Use of Insulin in the Treatment of Psychoses," and Gilbert L. Sandritter, "What Can We Do About Mental Illness in the Future?"

### NEW JERSEY

**State Society Studies Cash Indemnity Plan**—A voluntary health insurance program to defray medical costs for the low wage group is under consideration by the Medical Society of New Jersey, it was recently announced. The society's insurance committee is consulting consumer groups, economists, insurance executives and others in an effort to work out a plan that will be acceptable and workable. On the basis of present studies it is thought that 4 cents a day may prove adequate as a premium base. For the indigent, who would not be able to participate in this type of insurance, the society is advocating state financial assistance on the plan that was used in 1934 and 1935, under which the indigent were cared for by their own physicians on a reduced fee basis. The society has also approved hospitalization insurance.

### NEW YORK

**Society News**—Dr. Arthur W. Booth, Elmira, Chairman of the Board of Trustees of the American Medical Association, addressed the Medical Society of the County of Erie, Buffalo, January 16, on recent events relating to medical practice.—Dr. Byron P. Stookey, New York, addressed the Medical Society of the County of Westchester, White Plains, January 17, on "Hermation of the Nucleus Pulposus."—Dr. J. E. G. M. Bullowa, New York, addressed the Medical Society of the County of Nassau in Garden City, January 31, on "Serum Therapy and Chemotherapy in Pneumonia."—Dr. Walter E. Dandi, Baltimore, addressed the Medical Society of the County of Albany in Albany, January 25, on "Diagnosis and Treatment of Lesions of the Cranial Nerves."

### New York City

**Section on Military Medicine Organized**—The Medical Reserve Officers of Kings County have organized a section on military medicine and surgery in the Medical Society of the County of Kings. The first meeting was held in October. At a meeting, January 16, Col. Adelino Gibson, U. S. Army, spoke on "Gas Attacks in Relation to the Civilian Population."

**Society News**—Dr. Eugene F. Traub, addressed the Society of Medical Jurisprudence, January 9, on "Dermatologist in Court, a Discussion of the Hazards Confronting the Dermatologist in His Practice and of His Problems When Testi-

ving as an Expert in Court'—At a meeting of the New York Surgical Society January 11 the speakers were Drs Rupert Franklin Carter, on "The Mikulicz Method Versus End-to-End Suture in Carcinoma of the Recto-Sigmoid" and Drs Howard A Patterson and Alexander Webb Jr, 'The Mikulicz Procedure for Carcinoma of the Colon—Late Results'

**New Health Buildings**—Mayor La Guardia recently laid the cornerstone for the Lower East Side Health and Teaching Center, which will operate in conjunction with New York University College of Medicine. This is the fifth unit in the health department's program to cooperate with the five medical schools of the city in the teaching of public health and preventive medicine. It is the eleventh of the department's district health centers. Three child health stations, two in Brooklyn and one in Queens, were opened in December, bringing the total number of these units to seventy. The buildings were erected by the WPA and the health department at a cost of \$50,000 each.

**New York University Alumni Day**—The Alumni Association of New York University College of Medicine announces its annual Alumni Day February 22. Influenza pneumonia and lung abscess will be discussed at morning and afternoon scientific sessions. The speakers at the morning session will be Drs Irving Graef, George P. Robb, Israel Steinberg, Jesse G. M. Bullock, William S. Tillett and Thomas Francis Jr. At a luncheon in the Wyckoff Memorial Lounge the following will speak: Harry Woodburn Chase, Ph.D., chancellor of the university; Drs Currier McEwen, dean of the medical school, Samuel A. Brown, dean emeritus and Howard Fox, president of the Medical Society of the County of New York. In the afternoon there will be a clinic and case demonstrations at Bellevue Hospital. Drs James Burns Amberson Jr and Thomas J. Galvin will speak on lung abscess and Dr. Charles Hendee Smith on 'Subacute Pneumonia in Children'.

## OHIO

**Personal**—Dr Henry P. Worstell, Columbus has been appointed assistant supervisor of the medical section of the state industrial commission succeeding Dr Roy J. Secrest, who resigned to enter private practice in Columbus.—Dr Sterling B. Taylor, Columbus was honored at a testimonial luncheon January 5 on his retirement as local surgeon for the New York Central Railroad after nearly fifty years of service.

**Society News**—Dr John A. Toomey, Cleveland addressed the Academy of Medicine of Cincinnati January 10 on "Management of Some Acute Contagious Diseases and Their Complications." Dr Karl A. Menninger, Topeka, Kan. will address the academy February 21 on "The Concept of Organic Suicide."—Drs Wyman C. C. Cole and David C. Kimball, Detroit, addressed the Montgomery County Medical Society, Dayton January 20, on "Studies in Neonatal Asphyxia."—Dr Jonathan Forman, Columbus, was the speaker at the annual banquet of the Mahoning County Medical Society, Youngstown, January 17, his address was entitled "Uncle Sam M.D."

**Forum on Allergy**—Physicians interested in allergy were invited to attend the North Central Forum on Allergy in Toledo January 15, arranged by allergy societies of Cleveland, Chicago, Michigan and the Ohio Valley Society of Allergists. The following program was presented:

- Dr Samuel M. Feinberg, Chicago, Diagnostic Measures
- Dr George I. Waldbott, Detroit, Value of Skin Tests in Diagnosis of Food Allergy
- Dr Jonathan Forman, Columbus, Dietary Management of Food Allergy
- Dr John H. Mitchell, Columbus, Drug Hypersensitivity
- Dr Milton B. Cohen, Cleveland, Preparation of Protein Extracts
- Dr Lloyd E. Seyler, Dayton, Preparation of Plant Oil Extracts for Diagnosis and Treatment

It was decided to make the conference an annual affair. The 1940 meeting will be in Chicago under the direction of Dr Tell Nelson. Ninety-nine physicians registered in Toledo.

## PENNSYLVANIA

**State Tuberculosis Meeting**—The annual meeting of the Pennsylvania Tuberculosis Society will be held in Pittsburgh February 14-15. At the first session Tuesday afternoon the topic for discussion will be "The General Practitioner of Medicine in Discovery and Treatment of Tuberculosis" and the speakers include Drs Horton R. Casparis, Nashville, Tenn., Bruce H. Douglas, Detroit, Herbert R. Edwards, New York, and Frank W. Burge, Philadelphia. At a morning session February 15 Mr. Holland Hudson, director of rehabilitation service, National Tuberculosis Association, New York, Mr. Mark Walter, state bureau of rehabilitation, Harrisburg,

and David K. Bruner, Ph.D., department of sociology, University of Pittsburgh, will discuss "Rehabilitation of the Tuberculous." At a luncheon session Drs Clarence D. Selby, Detroit, and Max R. Burnell, Flint, Mich., will speak on "Tuberculosis in Industrial Health Service."

## Philadelphia

**Personal**—Dr Winifred Bayard Stewart, assistant clinical professor of neurology at the Woman's Medical College of Pennsylvania, has been appointed psychiatrist at the Philadelphia General Hospital.

**Hospital News**—A new \$56,000 building for the school of nursing of the Pennsylvania Hospital was recently dedicated. It was named in memory of Dr. Richard H. Harte who died in 1925. The building was made possible by contributions from Dr. Harte's family, from Caroline McKee, a graduate of the school from Mr. William H. Donner and from a bequest from Mrs. E. Walter Clarke.

**County Society Ninety Years old**—The Philadelphia County Medical Society celebrated its ninetieth anniversary at a meeting January 27. Dr. George Morris Piersol, professor of medicine, University of Pennsylvania Graduate School of Medicine, gave an address on "The Importance of Postgraduate Medical Education" and Dr. Wilmer Krusen, president of the Philadelphia College of Pharmacy and Science, a historical address. Greetings were extended by representatives of various Philadelphia organizations.

## Pittsburgh

**New Municipal Hospital Assured**—Donation of a site by the University of Pittsburgh will make possible immediate construction of a new municipal hospital, according to *Pittsburgh's Health*. In May 1938 a bond issue of \$1,350,000 was voted and subsequently a PWA grant of \$578,000 was obtained. It is planned to have the laboratory of the public health department in the new hospital.

**Graduate Courses**—Eight graduate courses of from three to seven sessions each have been announced by the Allegheny County Medical Society for its thirteenth series. They began early in February and will continue with lectures once or twice a week. The subjects and instructors are:

- Dr. Stuart N. Rowe, Neurosurgery
- Dr. Howard G. Schleiter, Clinical Electrocardiography
- Dr. Curtis C. Meehling and associates, Office Proctology
- Drs. Joseph A. Hepp and Elvin J. Biteman, Office Gynecology, Including Practical Endocrine Therapy
- Dr. Watson Marshall, Diseases of the Ear, Nose and Throat
- Drs. Murray B. Ferderber, George G. Burkley and James A. Mansmann, Pneumonia and Its Management
- Dr. Robert C. Grauer, Diagnosis and Treatment of Endocrine Disorders
- Dr. Robert L. Anderson and associates, Diseases of the Male Genito-Urinary System

**Society News**—Dr. Priscilla D. White, Boston, was the guest speaker before the Allegheny County Medical Society January 17 on "Diabetic Children." Dr. Maud L. Menten spoke on "Studies on Immunization Against Scarlet Fever" and Dr. Jessie Wright on "The Use of the Hypertonic Salt Water Pool in the Treatment of Osteomyelitis."—At a meeting of the Pittsburgh Academy of Medicine January 24 the speakers were Drs. Nelson P. Davis and Howard H. Permar on "Primary Tumor of the Spleen," Harry R. Decker, "Foreign Bodies in the Heart" and Earl Vandegriff Wilkinsburg, Pa., "Congenital Deformities." Dr. Adelbert Boyd Miller Jr. presented a case report on osteomyelitis of the skull.—The problem of osteomyelitis was considered at a meeting of the Pittsburgh Orthopedic Club January 26 by Drs. Robert C. Grauer, George W. Grier, George V. Foster and Paul B. Steele.

## TEXAS

**Specialty Societies Meet**—The Texas Orthopedic Society met in Houston in November with Dr. Fremont A. Chandler, Chicago, as guest speaker. Dr. Chandler discussed cases presented by Houston physicians.—The Texas Neurological Society held its semiannual meeting Nov. 7, 1938 at the Terrell State Hospital, Terrell. The speakers, all of Austin, were Drs. Montelle I. Brown, on sterilization of the unfit, Emmett G. Ward, the work of the state school for the feebleminded, and Charles M. Covington, typhoid vaccine therapy in the treatment of dementia paralytica. Drs. Theodore S. Howell and Roy C. Sloan of the hospital staff presented cases from the institution.—At a meeting of the Texas Pediatric Society in San Antonio in October the guest speakers were Dr. Horton R. Casparis, Nashville, Tenn., on "Behavior Problems in Children" and "Tuberculosis" and Maurice L. Blatt, Chicago, on "Diarrhea in the Neonatal Period and Treatment and Care of the Premature Infant."—The annual meeting of

the Texas Radiological Society was held in San Antonio recently. Among speakers on the program were Drs Roy G. Giles, San Antonio, on "Roentgen Therapy in Essential Hypertension", Thomas B. Bond, Fort Worth, "X-Ray Treatment of Pneumonia" and Mr Mac F. Cahill, executive secretary, Intersociety Committee for Radiology, Chicago, "Economic Problems of Radiology." Dr Carroll F. Crum, Corpus Christi, was named president elect and Dr Jerome H. Smith, San Angelo, became president.

### WASHINGTON

**Dr Penney Honored for Service as Secretary**—The Pierce County Medical Society gave a banquet January 10 in honor of Dr Warren B. Penney, Tacoma, who is retiring after more than twenty years as secretary of the society. Dr Albert E. Hillis, Tacoma, presided and Drs Wilmot D. Reid, Joseph P. Kane and Edwin W. Jones spoke. Dr Penney was presented with a motion picture camera. He has been president of the Washington Tuberculosis Association and is a director of the National Tuberculosis Association and president elect of the Washington State Medical Association. Dr Blair Holcomb, Portland, Ore., addressed the society after the banquet on "Management of the Diabetic with Protamine Insulin."

### WISCONSIN

**District Meetings**—At a meeting of the First Councilor District of the State Medical Society of Wisconsin in Oconomowoc recently Dr Rogers T. Cooksey, Madison, demonstrated the use of instruments in the peritoneal cavity and Dr Harold E. Marsh, Madison, discussed typing and treatment of pneumonia. Drs William D. Stovall, William S. Middleton and Joseph W. Gale, Madison, presented a symposium on pneumonia at a meeting of the Ninth Councilor District of the State Medical Society of Wisconsin in Wisconsin Rapids recently.

**Personal**—Dr Donald R. Searle, Superior, has been appointed a member of the state board of medical examiners to succeed Dr Charles W. Giesen, Superior. His term will end July 1, 1941. Dr Clarence J. Combs, Oshkosh, was honored with a dinner and special program recently marking his retirement as commanding officer of the 370th medical regiment of the U. S. Reserve Officers Training Corps. Dr William D. Stovall, Madison, has resigned as chairman of the committee on cancer of the State Medical Society of Wisconsin after ten years' service.

### GENERAL

**Examination by Orthopedic Board**—The next examination of the American Board of Orthopedic Surgery will be held in conjunction with the meeting of the American Medical Association in St. Louis in May. Applications must be filed before April 1 with the secretary, Dr Fremont A. Chandler, 6 North Michigan Avenue, Chicago.

**Birth Control Agencies Merge**—The American Birth Control League and the Birth Control Clinical Research Bureau have merged to form the Birth Control Federation of America, following ratification by the league of the action of a joint committee presented at the eighteenth annual meeting of the league in New York January 18. Dr Richard N. Pierson, New York, chairman of the joint committee, was elected temporary president of the new federation and Mrs. Margaret Sanger, honorary chairman of the board.

**Mead Johnson Award in Pediatrics**—The committee on awards of the American Academy of Pediatrics announces rules and regulations governing the Mead Johnson Award for Research in Pediatrics, which was established at the annual meeting of the academy in 1938. Two awards will be given annually at the meetings of the academy, one of \$500 and one of \$300, for research work published during the preceding calendar year. The award is limited to workers in the United States and Canada and to investigators who have not been graduated more than fifteen years. Thus the award in 1939 will be given for research published during the period of Jan. 1 through Dec. 31, 1938, by a graduate of 1923 or later. Communications should be addressed to the chairman of the committee, Dr Borden S. Veeder, 3720 Washington Boulevard, St. Louis, Mo.

**Anthrax Traced to Japanese Shaving Brushes**—The U. S. Public Health Service announced recently that a death from anthrax in North Dakota had been traced to the use of a shaving brush made in Japan. Surgeon General Thomas Parran requested collectors of customs at all ports of entry

to bar such brushes until samples had been tested by the public health service. Tests of some samples showed that the brushes had not been sterilized. According to an announcement issued by the New York State Department of Health January 30 the brushes are 4½ inches long and the handles three-fourths inch in diameter, painted in colors. The lettering "Japan 332" is stamped on the top of each brush and on the sides appear the words "Imperial-Sterilized." Dealers and owners are asked to send any brushes of this description to the department of health.

**International Cancer Congress in September**—The Third International Cancer Congress under the auspices of the International Union Against Cancer will be held in Atlantic City September 11-16 with Dr Francis Carter Wood, New York, as president. The following sections have been proposed: general research, biophysics, genetics, general pathology of cancer, radiologic diagnosis, radiotherapy, statistics and education. Membership in the congress is secured by application to the secretary, Dr Donald S. Childs, 713 East Genesee Street, Syracuse, with remittance of \$15. Membership does not include the right to present a paper unless the paper or an abstract has been submitted to and approved by the program committee. All papers and abstracts as well as questions pertaining to them should be addressed to Dr Wood, 630 West 168th Street, New York. Dr Eldwin R. Witwer, Harper Hospital, Detroit, is chairman of scientific exhibits, and Dr Alfred L. Loomis Bell, professor of clinical radiology, Long Island College Hospital, Brooklyn, is chairman of commercial exhibits and transportation. Thomas Cook and Son—Wagon Lits are the travel agents.

**Changes in Status of Licensure**—The Indiana State Board of Medical Registration and Examination reports the following:

Dr Peter C. Berns, Linton, license restored Aug. 16, 1938.

Dr Sidney J. Eichel, Evansville, license restored Nov. 29, 1938.

The Kentucky State Department of Health recently reported the following action:

Dr William H. Ashby, Iewisport, license restored Aug. 11, 1938.

The State Board of Registration of Medicine of Maine reports the following:

Dr Atherton M. Ross, Farmington, license revoked Nov. 9, 1938, for violation of the state medical practice act.

The Minnesota State Board of Medical Examiners reports the following action:

Drs Kenneth V. Overend and Fred E. Myers, both of Hallock, Minn., licenses revoked Dec. 16, 1938. The evidence disclosed numerous cases of bilateral salpingectomies and other surgical procedures, some of which resulted in the miscarriage of the patients.

Dr Arthur W. Eckstein, Mankato, license revoked Dec. 16, 1938, for procuring and abetting a criminal abortion.

Dr Gottfried Schmidt, Lake City, license suspended for five years Dec. 16, 1938, having been found guilty of advertising professional superiority to and greater skill than that possessed by fellow physicians and surgeons and of conduct unbecoming a person licensed to practice medicine and detrimental to the best interests of the public.

The Board of Medical Examiners of New York recently reported the following changes in status of licenses:

Dr Peter E. de Mattheis, whose last recorded address was 109½ Liverpool Street, Jamaica, N. Y., license canceled because of narcotic addiction.

Dr Julius Miltz, New York, license suspended for one year on the basis of fraud and deceit; he was convicted of conspiracy and petit larceny and received a suspended sentence.

Dr Samuel L. Fruchs, New York, license suspended for one year on the basis of fraud and deceit.

Drs Peter H. Friedman, Deal, N. J., Victor L. Lub, Gross, Joseph A. Zlinkoff, Alexander Reiss and Louis Greiner, all of New York, licenses suspended for varying periods on the basis of offers to perform criminal abortion.

Dr Edmund K. Macomber, whose last known address was 745 New Scotland Avenue, Albany, license revoked Nov. 16, 1938.

The Public Health Council of West Virginia recently reported the following action:

Dr Elias Benjamin Thompson, Williamson, license restored Oct. 31, 1938; it had been revoked March 2, 1937, for violation of the narcotic laws.

Dr Chester D. Wainwright, Charlestown, license revoked Oct. 31, 1938, for commission of a felony.

The Wisconsin State Board of Medical Examiners recently reported the following action:

Dr Raymond J. Henderson, Tomahawk, license restored November 4.

### CORRECTION

**Erythrol Tetramtrate in Angina Pectoris**—In the abstract of this title from *Ugeskrift for læger*, Nov. 17, 1938, which appeared in *THE JOURNAL* January 28, page 374, the dose of erythrol tetramtrate was given as from 7.5 to 15 Gm. three or four times daily. This should have read from 7.5 to 15 mg.

#### Cancer Research

The thirty-sixth annual report of the Imperial Cancer Research Fund shows important advances

##### CARCINOGENESIS

In 1936 Selbie, working in the laboratories of the fund, published observations on the carcinogenic action of colloidal thorium dioxide which confirmed the observations of French observers. The substance is used by radiologists, who inject it into the veins or into the brain to reveal structures not visible in ordinary roentgenograms. It remains in the body indefinitely after operation. In rats and mice it produces sarcomas at the site of injection in a large proportion of cases. The thirty-fourth annual report contained a warning against the practice of leaving radioactive substances in the human body, because of the danger of producing malignant growths. Dr Leslie Foulds is preparing for publication an account of the production of malignant tumors in guinea pigs by colloidal thorium dioxide. He injected small quantities into the bases of the nipples of females and obtained one carcinoma and three sarcomas. One of these tumors was removed more than three years after injection, when it was still small, and it proved to be sarcoma. Thus the danger of colloidal thorium dioxide may be long delayed even in laboratory animals, which respond much more quickly than man to carcinogens. A period of ten or fifteen years might be expected before colloidal thorium dioxide produces a tumor in man, and since it has not been in use so long it is premature to conclude that it is harmless. In America the danger of thorium dioxide and its disintegration products has been shown by the production of malignant tumors in workers who handle luminous paints.

##### THE DEVELOPMENT OF CANCER PREVENTED BY A HORMONE

The changes in the ductless glands after an animal has been treated with estrone over a long period were recorded in the thirty-fifth annual report. Dr William Cramer and Dr E S Horning have continued their studies of these changes during the past year. Previous observations had shown that prolonged treatment with estrone produces enlargement of the anterior lobe of the pituitary, with disappearance of the granular acidophil cells, degenerative changes in the adrenals and mammary cancer. This suggests a physiologic antagonism between estrone and the hormones produced by the pituitary acidophil cells. Experiments with mice proved this to be correct. The simultaneous administration of the thyrotropic hormone of the anterior lobe and estrone prevented both proliferation of the mammary epithelium and degranulation of the anterior pituitary cells, changes readily produced by estrone alone. These observations were used to prevent spontaneous cancer in a strain of inbred mice with a high incidence—about 60 per cent in breeding females. It was thus proved that the thyrotropic hormone which stops the action of estrone on the pituitary and the mammary gland also prevents the development of cancer.

#### Carcinogenicity of a Tar-Creosote Mixture Used by Fishermen

Dr Stephan Beck, working at the research department of the Glasgow Royal Cancer Hospital, reports in the *British Medical Journal* an experiment with an important practical bearing. Dr C C McKenzie of Campbeltown, Scotland, suspected that a tar-creosote mixture used by the local fishermen was responsible for cases of cancer of the lip. In mending their nets they put the bone or wooden needle, threaded with tarred twine,

between their lips. The carcinogenicity of the mixture was tested by painting it on the interscapular region of thirty mice. After the second application severe dermatitis, ending in ulceration, was produced. After 106 days the first papilloma occurred. In his pathologic report Dr L W Price stated: "This is a keratinizing epithelial papilloma, showing very early malignant change. Eleven papillomas developed in these mice from the 106th to the 349th day. The histology was that of well differentiated squamous carcinoma." It was therefore concluded that the tar-creosote mixture which came into contact with the lips of the fishermen was carcinogenic and that this source of cancer should be eliminated. It is necessary either to produce a non-carcinogenic tar, possibly by distillation at lower temperatures than at present, or to educate the fishermen to abandon the habit of putting the needle threaded with tarred twine between their lips when mending their nets.

#### Medical Demand for Deep Shelters from Air Raids

While all other precautions for the protection of the civil population against air raids are being expedited, little is being done toward providing deep underground shelters. In the cities and particularly in London the difficulty and expense of providing such shelters for the population in general would be immense. The government is proceeding with a scheme for steel shelters which would protect against the blast and fragments from shell explosions but not from direct hits. Twenty-one London hospital physicians have sent a joint letter to the press pointing out that air raids would produce an enormous number of casualties. Great numbers of civilians would be killed or injured by the high explosive bombs, disabled by the shock or concussion, or buried beneath fallen buildings, in which the danger of fire would be considerable. The morale of even highly trained troops cannot be maintained against continuous bombardment without adequate protection. How can women and children be expected to endure similar trials? British physicians probably could not cope with the number of casualties under the present conditions. The signatories hold that fully efficient medical and surgical treatment cannot be given unless adequate bomb proof shelters are provided for those who cannot be promptly evacuated from danger areas. These shelters must be deep enough to prevent penetration and sufficiently numerous to be quickly reached. They could be constructed beneath buildings as well as under squares and open spaces. Some should be designed for medical purposes, as the hospitals may be so damaged as no longer to provide facilities for the treatment of casualties or even for their safety.

##### PSYCHIATRIC CASUALTIES

A committee of the psychiatrists of the London hospitals is considering the effects of air raids on the civilian population. The committee believes that it will be impossible to estimate the number of psychiatric casualties. According to some there are likely to be at first three for every physical casualty. At present there is no official list of psychiatric-trained physicians, and the committee asks that a personnel be trained in time of peace in the elements of mental nursing and the handling of such cases.

##### PSYCHIATRIC WAR PREPARATIONS

What is called civilized war has only increased the horrors of warfare, while man has become more subject to neuroses. In 1918 there were more than 70,000 British patients under treatment. The Tavistock Clinic (Institute of Medical Psychology) has arranged a course of lectures for physicians on neuroses in war time, which is designed to give insight and instruction to those who may suddenly be called on to deal with such problems. The subjects selected for the lectures are 'War and the Civilian Population', 'Conversion Hysteria', 'Physical and Psychotic Syndromes', 'General Etiology and Psychogenesis of the Psychoneuroses', 'Anxiety States' and 'Emergency Treatment of Neurotic States'.

## Medicosocial Aspects of Latent Adrenal Insufficiency

A paper was read at the Dec 6, 1938, meeting of the Académie de médecine de Paris by Drs Pierre and Camille Chatagnon. The authors had the opportunity to observe patients who presented the clinical picture of adrenal insufficiency of congenital origin. Although they are unable to offer microscopic proof of their theory, the results of treatment justify the deduction that the symptoms were the direct result of an adrenal dysfunction.

The only symptom over a considerable period is the inability in both sexes and at all ages to make any sustained effort because of an excessive feeling of fatigue. The patient cannot carry out the physical or psychic efforts which any person of his age and physical development can do without experiencing an abnormal degree of fatigue, which is slow to disappear and necessitates a prolonged period of rest, preferably by lying down. Life expectancy is not interfered with, but such individuals are in a constant state of mental and physical asthenia. When they feel able to be active, they must conserve their strength lest an aggravation of the state of fatigue should occur. The clinical picture of such cases has been accurately described by Brossons. As to the hereditary factor, this seems to be predominantly paternal. One finds a congenital more often than an acquired insufficiency, the latter in the order of their incidence having as causes a typhoidal, tuberculous or syphilitic infection. It is difficult to detect the symptoms of such an adrenal dysfunction until after infancy. At a later period an excessive tendency to fatigue after mental or physical exertion is to be noted. Such children are inclined to be apathetic, and their desire to lead a sedentary existence is in sharp contrast to their apparently normal physical development.

It is especially during the school years that the following two types of latent adrenal insufficiency are to be looked for:

1. The pseudorobust type. The child appears normal but the physical resistance is minimal. Any physical effort is of short duration, accompanied by muscular pain which appears early and recedes very slowly. This physical deficiency is apparent when the child is called on to carry out any exercises, such as others do without any difficulty. The child feels sleepy at all hours and is inclined to lie down. He becomes introspective, even depressed and resigned to lead an inactive life. In their school work such children appear normal so far as the acquisition of knowledge is concerned, but any sustained effort such as an examination tires them much more than it does other children.

2. The pseudolazy type. The sensation of fatigue following any effort causes the child to limit its activity to the minimum, keeping him from joining in games. Such children fall asleep in school or while doing home work and are difficult to arouse in the morning. The adrenal dysfunction is invariably accompanied by disturbances of the genital functions as puberty approaches. Toward middle age there is a repetition of all the symptoms observed earlier, such as the lack of desire to do anything requiring mental or physical effort. These individuals are unable to concentrate and may become melancholic. They often complain of symptoms of vasomotor origin such as headaches, flushes and tendency to perspire easily.

It is of the utmost importance for the educator and social worker to keep these two types in mind and not to ascribe the desire to avoid physical or mental effort to laziness or lack of ambition. The treatment is preventive and includes a mode of living in which there is as little excitement as possible, an ample and carefully selected diet and the administration of adrenal preparations combined or not, according to the individual case, with the use of ovarian or testis preparations and of vitamin C.

## Changes in Paris Hospital Staffs

Owing to the retirement of Prof Georges Marion as head of the urologic department of the University of Paris Medical School, the clinical teaching in this specialty will be given at

the Hôpital Cochin by Prof Maurice Chevassu, who is the successor of Professor Marion. Professor Heitz Boyer, having reached the age limit for associate professors, will also retire and his successor at the Hôpital Lariboisière is Prof Bernard Fey. Dr Gouverneur will take charge of Professor Marion's service at the Hôpital Necker and Dr Louis Michon will replace Dr Gouverneur at the Hôpital St Louis. These changes, which were effective January 1, will interest American urologists who desire to visit the Paris clinics.

## Officers in Paris Societies

At the recent annual meeting of the Académie de chirurgie, Prof Raymond Gregoire was elected president and Prof Pierre Mocquot vice president.

The officers for 1939 of the Académie de médecine are Inspector General Sidur president and Prof Louis Martin, director of the Pasteur Institute of Paris, vice president.

At the annual meeting of the Société médicale des hôpitaux de Paris, Prof Pierre Lereboullet was elected president for 1939 and Professor Laignel-Lavastine vice president.

## Research on Gifted Persons

The newest aspect of genetic research is so called research on hereditarily gifted persons. Its purpose is to make a systematic selection of the gifted which, independent of the material circumstances of the individual person, makes possible the development of talent appearing anywhere within the nation as a whole. To this end a cooperative organization has lately been established which has at its head the director of the "fostering of talent" department of the "central headquarters of national occupational competition." Uniform standards (political and otherwise) to govern the selection of talented persons who may be aided by the state are to be worked out by this "cooperative association for research on inherited talent." In this activity the new organization collaborates with the racial-political bureau of the Nazi party, the central bureau of race and settlement of the *Schutzstaffeln*, the national public health service commission, the various vocational guidance centers, the German labor front, the national youth movement, the national student aid and the faculties of institutions of higher learning. On the occasion of the last national occupational contest 5,000 persons who qualified as superior workers in their respective occupations were required to fill out special heredobiologic questionnaires containing detailed questions with regard to siblings and parents, general education and vocational training, childhood residence in big city, medium sized city, small town and country, occupational activity, and so on. Information about the grandparents was also requested.

## The Purge of Jewish Dentists

In an early December issue of *Zahnärztlichen Mitteilungen* the question of an expulsion of Jews from the dental profession was discussed. The recent legislation directed against Jewish physicians (*THE JOURNAL*, Dec 24, 1938, p 2405) has not been applied to Jewish dentists. *Zahnärztlichen Mitteilungen* holds it now to be self evident that the problem of the Jewish dentists must also be brought to "a solution compatible with German national sensibilities." Regulation similar to that which has taken place in the medical profession is therefore in order. As of November 9, there were reported to be 211 Jewish dental practitioners in Berlin, these men represented a large part of the 449 Jews registered as dentists in the old Reich. Since the proportion of Jewish dentists is so small, their exclusion from practice will in no way jeopardize the dental care of the nation as a whole. It is impossible at the moment to

state the exact number of Jews actively practicing dentistry in Austria and in the Sudetenland, they are not included among the mentioned 449 Jewish dentists. One cannot doubt the imminence of a purge of the dental profession analogous to that which has already been effected in the medical profession.

#### The Prognosis of Tuberculosis in Infants

Dr Beltle of Munich assembled data on 514 nurslings and infants who had been hospitalized for treatment of tuberculosis of the glands, lungs, hilus, bones or joints. It was possible to make follow-up examinations of 496 of these children from one to eight years after occurrence of infection and after onset of illness. At the follow-up survey, 469 of the 496 children were still living. In 444 children, most of them in a good state of nutrition, the tuberculosis was inactive. In twenty-two children active tuberculosis was observed at the follow-up but in only two cases was the prognosis regarded as unfavorable. Tuberculosis with certainty had caused the deaths of eighteen of the twenty-seven children who died. Dr Beltle submits the following data on the lethality. Of ninety-six children who became tuberculous during the first year of life, eight (8.3 per cent) died, of 133 children infected during the second year, eight (6 per cent) died, of 266 children infected from the third to the sixth year, two (0.75 per cent) died. These investigations show that the prognosis for the tuberculous nursing or infant is much more favorable than is generally assumed on the basis of the literature.

#### Establishment of a National Tuberculosis Council

At the end of November a national tuberculosis council was established for the purpose of a more uniformly organized campaign against the disease. Among the council members are the national minister of the interior representing the reichsführer, the national minister of labor, and the national minister of publicity and propaganda. The presiding officer is Ministerial-Director Gutt, M.D., of the national ministry of the interior. The duty of the new board is to organize a carefully planned nationwide campaign against tuberculosis, to set up cooperative antituberculosis units in the various German states and provinces and in addition to act in a supervisory capacity, namely to see that all suitable measures are carried out.

In Thuringia, Central Germany, a special appropriation has made it possible for the state to assume the entire cost of a course of therapy or hospitalization for needy and uninsured tuberculous patients who belong to the lower economic groups or are impecunious members of the middle class. Adequate treatment is thus assured every tuberculous person in Thuringia. In addition it is planned to place in service a mobile x-ray examination laboratory, the first of the kind in Germany. The home of this traveling unit will be a motor truck trailer. With the x-ray apparatus it will be possible to take some 120 pictures 35 cm by 35 cm within an hour.

#### Campaign Against Contagious Diseases

The national minister of the interior has issued a decree effective January 1 with regard to the campaign against contagious diseases. This legislation contains specific provisions destined to help combat undulant fever, diphtheria, epidemic encephalitis, epidemic cerebrospinal meningitis, whooping cough, puerperal fever, poliomyelitis, trachoma, bacterial food poisoning, malaria, anthrax, paratyphoid glanders, relapsing fever, contagious dysentery, scarlatina, rabies, trichinosis, tuberculosis, tularemia, typhoid and Weil's disease. Similar national legislation heretofore in force dates back to 1900 and is more limited in its scope, being concerned only with the (in general) more dangerous infectious diseases (leprosy, cholera typhus, yellow fever, plague and variola). According as the public health services have become so well stand-

ardized for the entire reich, the moment is propitious for an expansion of the nation-wide legislation initiated by the statute of 1900. Thirty-eight years ago authoritative opinion considered several contagious diseases to be of minor importance and went to appear only in local outbreaks or isolated cases. Accordingly the 1900 statute included no provisions designed to combat these diseases. Today the older view in this regard is no longer tenable. The increase in communications has favored the general diffusion of contagious diseases and as a consequence the transmissibility of many diseases which were not regarded as contagious in 1900 is now conceded. Local regulations are therefore no longer adequate. The new legislation provides unified combative measures against diseases indigenous to Germany as well as those which threaten to enter from abroad. The older statute will still remain in force.

#### Semmelweis and Cederschjold

In a lecture at the Congress on Puerperal Fever in Strasbourg Aug 2-4, 1923, E. Hauch, professor at the University in Copenhagen, stated that a new discoverer of the cause of puerperal fever had been found in the person of Pehr Gustav Cederschjold. Thereupon Tiborius Gyory, professor of medical history at the University of Budapest, resolved to defend the memory of Semmelweis and the results of extensive investigation into this matter were published recently. Cederschjold was born in 1782 in Lidboholm, Sweden. He studied in Lund, Sweden, where he graduated as doctor of medicine in 1809. For graduate study in obstetrics and gynecology he went to Copenhagen to the institute of Johannes Sylvester Saxtorph. At this time Cederschjold already was studying the question of puerperal fever and in 1811 he published a treatise. Returning to Lund he was prosecutor for a time, in 1813 he moved to Stockholm, where he practiced obstetrics. In 1817 the king of Sweden appointed him extraordinary professor of obstetrics and adjunct of the lying-in hospital Allmänna Barnbordshuset. In 1822 Alm died and Cederschjold became regular professor and director of the lying-in hospital. In 1829 he arranged with king Charles XIV that Swedish midwives be permitted to perform forceps operations in districts where there were no physicians. In his first report he mentioned 140 midwives, who performed forceps operations on 252 women, of whom twenty died. He also wrote an obstetric manual of three volumes which for a long time was used by students. Cederschjold died in 1848.

The devastation of puerperal fever did not spare the Scandinavian countries in the eighteenth and nineteenth centuries, though the mortality did not reach the frightfully high rates for Paris and Vienna. At Allmänna Barnbordshuset, founded in Stockholm in 1775, the mortality from puerperal fever in the first two years was 2 per cent, while in 1777, when the institute occupied a new building, it was 19 per cent. From this time on the disease was constantly present in the institute and it was natural for it to be in the foreground of Cederschjold's interest. In his textbook he wrote: 'It seems that puerperal fever may assume a lasting epidemic character in bigger lying-in hospitals, spread not only by way of a volatile agent through the air or through the ward miasmas, but chiefly when the disease assumes the picture of putrescence of the womb and the more adherent infecting agents or the so called contagions, cleave from the vulva to the nurse, who carries them to healthy mothers in cleaning their vulvae with the same sponge or towel or simply in manipulation without having washed their hands after having dealt with patients suffering from puerperal fever. I myself experienced this several times having seen that almost all lying-in wives fell sick when they were treated by a certain midwife so that I was forced to prohibit her from visiting the

obstetric wards At the same time the morbidity rate for lying-in wives attended by the best of the midwives was unimportant The presence of contagion in the offensive vapor noted at the postmortem examination of those dead of puerperal fever was proved according to my opinion by the speed with which the epidemic increased after postmortem examinations, though performed in far flung localities so that finally postmortem examinations had entirely to be stopped This view has been supported by the observation of my adjunct Idstrom, who once in my absence had to visit five wives at their homes who a short time before had been inmates of the lying-in hospital, all had fallen ill with puerperal fever and only one of them survived"

His belief that the contagion was spread from the vulva induced Cederschjold to supply every patient with a special towel and to oblige the midwives to use separate sponges and towels for each patient The favorable results of this method were seen shortly

In an important chapter in Cederschjold's book he wrote "About the end of 1826 on my repeated request the board of the institute allowed three ground floor wards which were wholly separated from the lying-in institute to be used exclusively for feverish lying in women The wards had nurses and midwives who served them exclusively Since then all wives suffering from puerperal fever have been accommodated there In later times I mixed some chlorine in the water with which the genital parts of the lying-in women were washed" Cederschjold gave an account of his method in the Swedish language in 1839 The discovery by Semmelweis was made in 1847 Semmelweis wrote "In order to crush the cadaver fragments adhering to the hands about the middle of May 1847—I do not remember the exact day—I used chlorina liquida, with which I and all my students had to wash their hands" Doubtless Semmelweis did not know of Cederschjold's work The most northerly follower of Semmelweis was Pippingsskold, obstetrician to the Helsingfors general hospital, to whom Semmelweis referred in an open letter addressed in 1862 to all professors of obstetrics In the book by Heinrichus on the history of obstetrics and gynecology in Finland published in Helsingfors in 1903, mention is made of the fact that Semmelweis could have come in contact with Pippingsskold in 1861, after the appearance of Semmelweis's main work The entire independence of the two discoverers is evident Chlorine lavage had been prescribed by Cederschjold for the washing of the genitals only, while Semmelweis built up a system for disinfection of the hands of those dealing with lying-in women It is certain that Cederschjold deserves a distinguished place in the long line of development, which from the labyrinth of fantastic theories led to the clarification of the prophylaxis and etiology of puerperal fever, at the peak of which is the Hungarian obstetrician Semmelweis

Essen-Moller, professor at the university in Lund, Sweden, devotes the first chapter of his book "Forelasningar i Obstetrik" (1934) to the memory of Semmelweis At the end of the book he mentions Cederschjold as follows "It is probable that it was not so written in the book of stars that the epoch of the history of puerperal fever should take its root in Sweden But as we honor now the work of Semmelweis, perhaps we Swedes have the right with satisfaction to think that in the barren soil of Ultima Thule the seed started to germinate earlier, though it did not grow to such a spreading tree, in the shadow of which mothers with their children can sit now in safety But what does this mean? The nourishment circulating in the tree of science comes from different soils and from different countries, who would dare to separate it into its constituents? Even if the tree casts its branches over the whole earth, we can be sure that the fruits picked from it were produced by common work and were ripened by common supervision Therefore every nation and every man who advanced the work is entitled to a share in the common achievements"

### Epinephrine Treatment for Malaria

Prof Maurizio Ascoli, in a lecture at the military hospital, spoke on the treatment of chronic malaria and malarial splenomegaly by means of intravenous injections of epinephrine Clinical observations are made in the Palermo hospital on soldiers as they come home from Africa who are suffering from malaria and who are receiving the epinephrine treatment Satisfactory results from the treatment are reported from Greece, the Belgian Congo, Trans-Jordan, Turkey and Italy The treatment consists of intravenous injections of epinephrine alone or in association with small doses of quinine As a rule the size of the spleen diminishes, the patient gains weight and his general condition improves The action of quinine is strengthened by epinephrine Quinine by itself, which was administered in one case for four consecutive months in daily doses of 1 Gm, failed to control fever When the combined quinine and epinephrine treatment was administered fever disappeared in two days The therapeutic effect of epinephrine does not depend on contracture of the spleen but on the increase of the forces of defense caused by epinephrine Dr Ballero has reported recurrences in 5 per cent of his cases in which the combined epinephrine and quinine treatment was administered as against 40 per cent in the cases in which quinine alone was given When pregnant women with malaria have the combined epinephrine and quinine treatment the latter does not interfere with the normal evolution of pregnancy and the development and health of the fetus The treatment is economical and well tolerated by the patients

### Surgery in Military Hospitals

According to statistics of the General Center of Public Health, 7,623 major surgical operations and 9,657 minor operations were performed in 1937 in Italian military hospitals Operations on the abdomen totaled 3,885 and those for hernia 2,004 Inguinal or inguinoscrotal hernia was complicated by varicocele in 142 cases, by hydrocele in twelve cases, by testicular ectopia in twenty eight cases and by cysts of the spermatic cord in eight cases In the fourteen cases of strangulated inguinal hernia the operation was successful For non-strangulated hernia the mortality was 0.2 per cent Operations on the appendix numbered 1,659, with a mortality of 1.4 per cent and on the abdomen (for gastric and duodenal ulcer, abdominal trauma and diseases of the digestive tract) 140, with a mortality of 19 per cent Of 203 operations on the cranium 174 were for mastoiditis, with a mortality of 2.87 per cent Mammectomy, including axillary dissection, was done in two men suffering from fibroma of the breast with a tendency to degenerate Operations were performed in seven cases of echinococcosis of the lung, in eleven cases of echinococcosis of the liver and in five cases of hepatic amebiasis

## Marriages

JOHN F. SHROTS, Woodstock, Ill., to Miss Olive C. Hosman of Omaha, Neb. in November 1938

EDWARD R. KRUMBIEGEL, Milwaukee, to Miss Callista Purtell of Hartford, Wis., Nov. 24, 1938

ROBERT M. STEWART, Kimball, S. D., to Miss Marjorie Helen Deuth in Chicago, Dec. 10, 1938

ANDREW MORRIS RYAN to Miss Phyllis Jane Bacon, both of San Francisco January 7

FREDERICK J. HOFMEISTER to Miss Viola Seymer, both of Milwaukee, Nov. 19, 1938

GERALD A. HANCUR to Miss Virginia Guido, both of Cicero, Ill. Nov. 26 1938

## Deaths

**John Signorelli** ☉ New Orleans, Tulane University of Louisiana School of Medicine, New Orleans, 1912, clinical assistant in pediatrics at his alma mater, 1912-1914, professor of pediatrics, Louisiana State University Medical Center, at one time professor of pediatrics at the Loyola Post-Graduate School of Medicine, member of the American Academy of Pediatrics, past president of the Louisiana State Pediatric Society, served during the World War, medical director of the parish public school system, served at various times and capacities on the staffs of the State Charity Hospital, Hotel Dieu, Southern Baptist Hospital, French Hospital and St Vincent Infant Asylum, aged 49, died, Dec 13, 1938, of complications following pneumonia

**Lucy Du Bois Porter Sutton**, New York, Cornell University Medical College, New York, 1919 assistant professor of pediatrics at the New York University College of Medicine, secretary of the section on pediatrics, New York Academy of Medicine, member of the American Academy of Pediatrics, chief of the cardiac clinic of the children's medical service, Bellevue Hospital, editor of the *Bulletin of the American Heart Association*, co-author, with Dr Charles H Smith, of a volume on heart disease in infancy and childhood in "Clinical Pediatrics", was known for her work on rheumatic fever and heart disease and for the treatment of chorea by induced fever, aged 47, died, Dec 23, 1938, in the New York Hospital, of monocytic leukemia

**Benjamin Franklin Baer Jr** ☉ Philadelphia University of Pennsylvania Department of Medicine, Philadelphia, 1903, member of the American Academy of Ophthalmology and Otolaryngology, associate professor of ophthalmology at his alma mater, and formerly associate professor of ophthalmology at the Medico Chirurgical College, Graduate School of Medicine, University of Pennsylvania, served during the World War since 1924 attending surgeon to the Wills Hospital aged 59, died, Dec 19, 1938, in the University of Pennsylvania Hospital of pneumonia

**Henry Woolfe Berg** ☉ New York, College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1881, instructor in infectious diseases, 1902-1906, instructor in contagious diseases, 1906-1908, instructor in diseases of children, 1908-1910, and associate in diseases of children 1910-1921, at his alma mater fellow of the American College of Physicians consulting physician to the Willard Parker Hospital and physician to the isolation service, Mount Sinai Hospital aged 79, died, Dec 22 1938, of myocarditis

**Frederick J Kalteyer** ☉ Philadelphia, University of Pennsylvania Department of Medicine, Philadelphia, 1895 Jefferson Medical College of Philadelphia, 1899, clinical professor of medicine at Jefferson Medical College of Philadelphia served at various times and in various capacities on the staffs of the Delaware County Hospital, Upper Darby, Pa St Joseph's Hospital, Philadelphia General Hospital, Frankford Hospital, St Mary's Hospital and the Pottstown (Pa) Hospital, died, Dec 20, 1938

**James Edwin Parker Holland** ☉ Bloomington, Ind, Indiana Medical College School of Medicine of Purdue University, Indianapolis, 1906, fellow of the American College of Surgeons, served during the World War ophthalmologist to the Bloomington Hospital university physician to Indiana University, aged 62, died Dec 4 1938, in the Methodist Hospital, Indianapolis, of acute coronary occlusion

**Harry Unger**, Patchogue N Y, Long Island College Hospital, Brooklyn, 1908, member of the Medical Society of the State of New York, served at various times and in various capacities on the staffs of the Jewish Hospital, King County Hospital, Bushwick Hospital and Caledonia Hospital Brooklyn and the Southside Hospital, Bay Shore aged 51, died, Nov 26 1938 of coronary sclerosis

**Victor G Veckl** ☉ San Francisco Medizinische Fakultät der Universität Wien, Austria 1881, member of the American Urological Association an Affiliate Fellow of the American Medical Association, member of the House of Delegates of the American Medical Association, 1913-1916, in 1919 and 1922-1929 aged 80, died Nov 16 1938 of cerebral anemia and arteriosclerosis

**Charles Franklin Applegate**, Los Angeles Medical College of Indiana Indianapolis, 1889, Bellevue Hospital Medical College New York, 1890 member of the American Psychiatric Association, at one time superintendent of the State Hospital Mount Pleasant Iowa, and State Hospital Norwalk Calif aged 73 died Nov 27 1938 of carcinoma of the prostate

**Alfred Frederick Allman**, Philadelphia Jefferson Medical College of Philadelphia 1895, assistant director of the department of public health, formerly assistant diagnostician for the department of health and police surgeon, at one time member of the state house of representatives, aged 73, died, Nov 17, 1938, of coronary obstruction and hypostatic pneumonia

**Wilson Ruffin Abbott**, Chicago, College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1904, member of the Illinois State Medical Society, at one time connected with the U S Public Health Service, and director of the U S Veterans' Bureau Hospital, number 55, Fort Bayard, N M, aged 65, died, Dec 5, 1938

**Charles Hill Suddarth**, Excelsior Springs, Mo., College of Physicians and Surgeons Medical Department Kansas City University Kansas City, Kan, 1898, member of the Missouri State Medical Association aged 69, medical superintendent of the Excelsior Springs Sanitarium and Hospital, where he died, Nov 25, 1938, of pneumonia

**Charles A Shultz**, Alvarado, Texas, University of Louisville (Ky) Medical Department, 1881, past president of the Johnson County Medical Society, formerly member of the city council, and health officer, at various times member and president of the board of education, aged 83, died Nov 21, 1938, of coronary thrombosis

**Martin W Barr**, Middletown, Del University of Pennsylvania Department of Medicine, Philadelphia, 1884, at one time chief physician to the Elwyn Training School, Elwyn, Pa, author of "Mental Defectives" and co author of "Types of Mental Defectives" aged 78, died, Dec 25, 1938, of cerebral hemorrhage

**Homer Scott**, Little Rock, Ark, University of Arkansas School of Medicine, Little Rock, 1913, member of the Arkansas Medical Society, assistant professor of obstetrics at his alma mater, served during the World War, member of the school board aged 57, died, Nov 1, 1938, of neurosarcoma of the mesentery

**Adelard Bernardin Cotnoir**, Riviere la Madeleine, Que, Canada, M B, Laval University Faculty of Medicine, Quebec, 1906 M D School of Medicine and Surgery of Montreal, Faculty of Medicine of the University of Laval at Montreal, 1908, aged 54 died in November 1938 of cerebral hemorrhage

**Frederick William Steinbock**, Avon by the Sea, N J, Maryland Medical College, Baltimore 1904, member of the Medical Society of New Jersey, aged 73, superintendent of the E C Hazard Hospital Long Branch, where he died, Nov 7, 1938, of chronic interstitial nephritis, myocarditis and uremia

**John Henry Woodcock** ☉ Hendersonville, N C, Hospital College of Medicine, Louisville, Ky, 1892, past president of the Henderson County Medical Society, served during the World War, formerly county health officer, on the staff of the Patton Memorial Hospital, aged 74, died, Nov 1, 1938

**Eugene E Shutterly**, Evanston Ill, Hahnemann Medical College and Hospital Chicago, 1888, served as health officer of Evanston on a part time basis during the year 1898 member of the first staff of the Evanston Hospital, aged 77, died, Nov 20, 1938, of coronary thrombosis and arteriosclerosis

**Otto Jacob Stein**, Palos Verdes Estates, Calif Missouri Medical College, St Louis, 1891 member of the Illinois State Medical Society, American Academy of Ophthalmology and Otolaryngology and the American Laryngological, Rhinological and Otological Society, aged 71, died in November 1938

**Peter Olaf Sundin** ☉ Los Angeles, University of Southern California College of Medicine, Los Angeles 1907, fellow of the American College of Surgeons aged 61, on the staffs of the Florence Crittenton Home and the California Hospital, where he died, Nov 29, 1938 of carcinoma of the stomach

**William A Purifoy**, Chidester, Ark Memphis (Tenn) Hospital Medical College, 1899, past president of the Ouachita County Medical Society, member of the Arkansas Medical Society, bank president, aged 68, died, Nov 25, 1938 in the Camden (Ark) Hospital, of cerebral hemorrhage

**Edward John Witt** ☉ Los Angeles, Rush Medical College, Chicago, 1896 member of the Michigan State Medical Society, formerly member of the board of education in St Joseph Mich at one time on the staff of St Joseph (Mich) Sanitarium, aged 68 died Nov 23 1938 of cerebral thrombosis

**Charles Emmett Jelm** ☉ Akron Ohio Ohio-Miami Medical College of the University of Cincinnati, 1912 member of the American Urological Association, fellow of the American College of Surgeons, on the staff of the City Hospital, aged 51 died Nov 22 1938 of heart disease

**Melville Ross**, Bloomington, Ind., Indiana University School of Medicine, Indianapolis, 1911, member of the Indiana State Medical Association, past president of the Monroe County Medical Society, served during the World War, aged 51, died, Nov 2, 1938, of cirrhosis of the liver

**Edward Everett Shell**, Prescott, Ark., University of Tennessee Medical Department, Nashville, 1894, member of the Arkansas Medical Society, on the staff of the Cora Donnell Hospital, aged 67, died, Nov 18, 1938, in Memphis, Tenn., of injuries received when struck by a truck

**Oscar Merle Shirey** ♂ Cleveland, Western Reserve University Medical Department, Cleveland, 1903, member of the American Academy of Ophthalmology and Oto Laryngology, served during the World War, on the staff of the Polyclinic Hospital, aged 60, died, Nov 20, 1938

**Stanley Wojcik Woyt**, Jackson, Mich., Wayne University College of Medicine, Detroit, 1933, member of the Michigan State Medical Society, aged 32, died, Nov 23, 1938, in the W A Foote Memorial Hospital, of injuries received when his automobile was struck by a truck

**Anthony Wayne Baugh**, Paoli, Pa., University of Pennsylvania Department of Medicine, Philadelphia, 1891, member of the Medical Society of the State of Pennsylvania, member of the House of Delegates of the American Medical Association in 1913, aged 71, died, Nov 8, 1938

**David Charles Simon**, Chicago, University of Illinois College of Medicine, Chicago, 1930, assistant in the department of medicine, University of Illinois College of Medicine, June 13, 1932-Sept 1, 1938, aged 34, died, Nov 17, 1938, of sarcoma of the mediastinum with metastasis

**James William Sullivan Stewart** ♂ 1st Lieut., M C, U S Army, Carlisle, Pa., Cornell University Medical College, New York, 1935, was commissioned a first lieutenant in the army June 2, 1937, aged 29, was killed, Nov 18, 1938, in an airplane accident near La Grange, Ga

**Michael Joseph Sheahan**, New Haven, Conn., Yale University School of Medicine, New Haven, 1896, served during the World War, on the staff of the Hospital of St Raphael, aged 69, died, Nov 13, 1938, of diabetes mellitus, arteriosclerosis and cerebral hemorrhage

**Richard Randolph Daly**, Atlanta, Ga., College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1888, member of the Medical Association of Georgia, served during the World War, aged 72, was found dead in November 1938

**William Field Taliaferro**, Beaumont, Texas, Tulane University of Louisiana School of Medicine, New Orleans, 1902, member of the State Medical Association of Texas, aged 59, died, Nov 21, 1938, in the Brackenridge Hospital, Austin, of coronary thrombosis

**William Edward Youngs**, Independence, Kan., Barnes Medical College, St Louis, 1899, member of the Kansas Medical Society, formerly mayor of Cherryvale, aged 66, on the staff of the Mercy Hospital, where he died, Nov 7, 1938, of coronary occlusion

**Octavius Lamar Williamson** ♂ Marianna, Ark., Tulane University of Louisiana School of Medicine, New Orleans, 1901, past president of the state board of health, past president of the Lee County Medical Society, aged 61, died in November 1938 of heart disease

**Peyton Jarrett Fullingim**, Dallas, Texas, Southwestern University Medical College, Dallas, 1909, member of the State Medical Association of Texas, served during the World War, on the staff of the Methodist Hospital, aged 60, died suddenly, Nov 24, 1938

**Ernest Peyton Jones**, Hermanville, Miss., Medical Department of Tulane University of Louisiana, New Orleans, 1887, member of the Mississippi State Medical Association, member of the board of health, 1899-1907, aged 73, died, Nov 10, 1938, of pneumonia

**John H Hunter**, Houston, Texas, Atlanta Medical College, 1888, member of the State Medical Association of Texas, Civil War veteran, formerly acting assistant surgeon in the U S Public Health Service, aged 86, died in November 1938 in a local hospital

**Joseph C Steuer**, Cleveland, Cleveland College of Physicians and Surgeons, Medical Department of the University of Wooster, 1895, aged 65, died, Nov 25, 1938, in the Mount Sinai Hospital of cholelithiasis, arteriosclerosis and bronchopneumonia

**Charles Wallace Poorman** ♂ Oak Park, Ill., College of Physicians and Surgeons of Chicago, School of Medicine of the

University of Illinois, 1903, on the staff of the West Suburban Hospital, aged 65, died, Nov 13, 1938, of coronary and cerebral sclerosis

**Edward Alfred Poret** ♂ Hessmer, La., University of the South Medical Department, Sewanee, Tenn., 1904, formerly member of the parish school board, aged 60, died, Nov 4, 1938, of carcinoma of the prostate with ulcerated metastasis to the liver

**Ernest Von Quast**, Kansas City, Mo., Missouri Medical College, St Louis, 1877, member of the Missouri State Medical Association, aged 85, on the staff of the Research Hospital, where he died, Nov 11, 1938, of arteriosclerosis and uremia

**Amos W Troupe** ♂ Pine Bluff, Ark., Rush Medical College, Chicago, 1884, president of the Jefferson County Medical Society, on the staff of the Davis Hospital, aged 82, died, Nov 21, 1938, of injuries received when struck by an automobile

**Jesse Andrew Randall**, Old Orchard Beach, Maine, Medical School of Maine, Portland, 1888, member of the Maine Medical Association, for many years member of the board of health, aged 74, died, Nov 27, 1938, of arteriosclerosis

**Willis Terry Zeigler**, Canton, Ill., College of Physicians and Surgeons, Keokuk, Iowa, 1896, member of the Illinois State Medical Society, formerly county coroner, aged 71, on the staff of the Graham Hospital, where he died, Nov 25, 1938

**Richard George Scribner**, Sacramento, Calif., University of California Medical School, San Francisco, 1921, member of the California Medical Association, aged 45, died, Nov 19, 1938, in the Sutter Hospital of coronary occlusion

**Etamar Mower**, Brookline, Mass., St Louis College of Physicians and Surgeons, 1921, member of the Massachusetts Medical Society, aged 43, died, Nov 29, 1938, in a hospital at Cambridge of acute coronary thrombosis

**Samuel M Rosenblum**, Chicago, Friedrich Wilhelms Universität Medizinische Fakultät, Berlin, Prussia, 1890, aged 62, died, Nov 25, 1938, in the Michael Reese Hospital of coronary sclerosis and bronchopneumonia

**Daniel Trigg Jr**, Bristol, Va., Medical College of Virginia, Richmond, 1903, served during the World War, aged 61, medical director and owner of St Ann's Hospital, where he died, Nov 4, 1938, of cerebral hemorrhage

**John Nelson Drury** ♂ Lowell, Mass., University and Bellevue Hospital Medical College, New York, 1904, formerly on the staff of the Bellevue Hospital, New York, aged 57, died, Nov 19, 1938, of coronary occlusion

**Luigi Carlo Paulino**, Los Angeles, Regia Università di Napoli Facoltà de Medicina e Chirurgia, Italy, 1899, aged 66, died, Nov 3, 1938, of acute pulmonary edema and hypertension

**Charles Rosenbaum**, Miami Beach, Fla., Columbia University College of Physicians and Surgeons, New York, 1910, aged 50, died, Nov 5, 1938, of hypertension and arteriosclerosis

**Sidney Burnett Tryon** ♂ Cooperstown, N Y., University and Bellevue Hospital Medical College, New York, 1908, aged 56, died, Nov 23, 1938, of arteriosclerotic heart disease

**Austin L Wray**, Rock Island, Ill., College of Physicians and Surgeons, Keokuk, Iowa, 1880, aged 86, died, Nov 4, 1938, of an infection which developed in an abrasion

**Timothy John Thurston**, Chicago, Dearborn Medical College, Chicago, 1907, aged 69, died, Nov 7, 1938, of endocarditis, diabetes mellitus and chronic nephritis

**Forrest Gabbert**, Louisville, Ky., Maryland Medical College, Baltimore, 1903, aged 67, died in November 1938 in the United States Marine Hospital of pneumonia

**Olive K Beers**, Albany, Ore., Willamette University Medical Department, Salem, 1890, formerly a missionary, aged 77, died, Nov 10, 1938, of mitral insufficiency

**Alvin Alfred Maples**, Clever, Mo., Barnes Medical College, St Louis, 1896, aged 68, died, Nov 24, 1938, of cerebral hemorrhage, arteriosclerosis and hypertension

**Lemuel C Kimberly**, Empire, Ga., Georgia College of Eclectic Medicine and Surgery, Atlanta, 1890, aged 76, died, Nov 11, 1938, of cerebral hemorrhage

**Charles M Beall**, Clarksburg, Ind., Cincinnati College of Medicine and Surgery, 1881, aged 84, died, Nov 15, 1938, of myocarditis and cerebral embolism

**Joseph Eldridge Warbritton**, Crosses, Ark. (licensed in Arkansas in 1903), aged 78, died, Nov 2, 1938, of senility

**Francis Albert Reed**, Eustis, Fla., Cleveland University of Medicine and Surgery, 1890, aged 71, died, Nov 8, 1938

**Harrison T Coop**, Newcastle, Texas, College of Physicians and Surgeons, Dallas, 1906, aged 67, died, Nov 5, 1938

**Andrew S Howard**, Simpsonville, S C., Atlanta Medical College, 1889, aged 77, died, Nov 2, 1938

## Bureau of Investigation

### THE C A WILLIAMS FRAUD

#### A Mail-Order "Cure" for Gonorrhea and Syphilis Barred from the Mails

The United States mails have been closed to the C A Williams Medicine Company of McKamie, Ark. This concern was started in 1929 by C A Williams a 70 year old Negro and in 1936 another Negro, Ples L Lewis, acquired a controlling interest. Apparently, neither man had even a high school education and no physician, pharmacist or chemist was employed in the business. On July 9, 1938, both men were called on to show cause why a fraud order should not be issued against their concern. On August 8 their attorney, Mr Mark P Friedlander, appeared in Washington for the hearing, on August 23 the mails were closed to the company.

The concern sold through the mails a group of alleged medicinal preparations for various diseases. The postal authorities directed their attention to three of the nostrums "Williams' System Tonic No 3," "Williams' Nerve Tonic No 4" and "Williams' Nerve Tonic No 1." The first of these three was represented as a cure for syphilis, gonorrhea, pellagra, "sores," "bad blood," boils, fevers and pains. It was found to be a solution of muriatic (hydrochloric) acid and green vitriol (ferrous sulfate). The second named product was found to be a red, syrupy liquid containing nux vomica, sugar and water. It was sold as a cure for "run down nature," nervous prostration, piles, paralysis, "wandering of mind" and "decline of sex force." The third product was the most expensive and was recommended as a "special" cure for gonorrhea and kidney complaints, it was found to consist of alcohol 42 per cent (the strength of much raw whiskey) with buchu and senna or rhubarb and flavored with cloves.

The concern obtained its victims in the usual manner. As the Solicitor for the Post Office Department put it in his memorandum to the Postmaster General recommending the issuance of a fraud order "Business is solicited by advertisements placed in various newspapers." One such advertisement sent to the Bureau of Investigation by a correspondent read

HEALS THOUSANDS  
Sores Weak Nature Syphilis Pellagra Gonorrhea Bad Skin  
Bad Blood Nervousness Indigestion Kidney Guaranteed Treat  
ment \$1.75 postpaid No C O D s

It was brought out at the hearing that the two Negroes bought their preparations from a St Louis drug company in gallon bottles and then Lewis in his house siphoned off the preparations in smaller bottles when needed.

The viciousness of selling alleged cures for such diseases as syphilis and gonorrhea must be obvious even to those without medical training. Even the attorney for these men admitted at the hearing that if he were buying from his clients' advertisements he "would expect something worthless."

### THE NATHAN PEIKES QUACKERY

#### The Mails Are Closed to a "Lost Manhood" Fraud

Nathan Peikes of Lowell, Mass., according to memoranda of Solicitors for the Post Office Department to the Postmaster General, has for some years past operated and controlled two concerns engaged in crude and indecent quackery of the 'lost manhood' type. Peikes' first company was known as "P P Products Company," which sold 'Nu-Gland Tablets' that were claimed to cure "quickly and lastingly" what Peikes called 'loss of vitality in men.' According to the records in the case business was obtained by means of magazine advertising and circular matter sent through the mails.

More than three years ago—Dec 11, 1935—a hearing was held in Washington in response to a charge by the Post Office Department to show cause why the mails should not be closed to the P P Products Company. Peikes did not appear at the hearing but was represented by his attorney, Mr Eugene C Brokmeyer of Washington D C who presented a written answer denying the charges. Mr Brokmeyer stated that he did not wish to enter on a formal trial of the matter but requested an extension of time to permit him to communicate with his

client with a view to submitting some additional proposal with respect to the disposition to be made in the case.

This was granted and on Dec 16, 1935, Peikes offered, through his attorney, to abandon his scheme and to direct the postmaster at Lowell to treat all mail addressed to the P P Products Company as "Refused" and to refuse to cash any money orders drawn in favor of the Company. As such a stipulation could be repudiated at the will of Peikes, the government refused to accept it. The Solicitor for the Post Office Department (Hon Karl A Crowley) in his memorandum to the Postmaster General recommending the issuance of a fraud order reviewed the evidence in the case and demonstrated the inherent fraudulence of the scheme. It was brought out that Nu-Gland Tablets were essentially a mixture of strychnine, iron, zinc phosphide and glandular material. It also was shown that Peikes was not a physician and had no physician connected with his company. As a result of the hearing a fraud order was issued closing the mails to P P Products Company on Dec 21, 1935.

But Nathan Peikes, figuratively speaking, thumbed his nose at the Post Office Department and by the simple expedient of changing the name of his company continued to swindle the public. The new trade name for Peikes' fraud was "Lee Products Company." He still advertised and sold Nu-Gland Tablets under representations identical with those of the P P Products Company. He also added to his armamentarium of fakery another product that he called "Lee's Vitam Perles" that were said to be "rich in vitamin E"—although government tests showed only a small amount present.

Some of Peikes' advertising matter read as follows:

#### LEES VITAM PERLES

Rich in Vitamin E	The Sex or Anti-Sterility Vitamin	Indications
Lack of Libido	Weak or Absent Erection	Sexual
Neurasthenia	Myasthenia	Gravis
Sterility	Female Sterility	Muscular Debility
		Male

Peikes led his dupes to believe that human beings were in grave danger of a deficiency of vitamin E in their diet. In order to give artistic verisimilitude to a bald and unconvincing narrative Peikes appended to his circulars a list of "Authorities Consulted"—of which the American Medical Association was the first given. Yet the simple facts are that in the 1938 edition of "Useful Drugs" published by the American Medical Association we read

'Vitamin E is present in many common foods but there is no established therapeutic indication for its use'

On July 15 1938, the Lee Products Company of Nathan Peikes was called on to show cause on August 17 why a fraud order should not be issued against it. This time Peikes did not, apparently, think it worth while even to employ an attorney, for no answer whatever was made to the charge and neither Peikes nor any representative appeared at the hearing. The Acting Solicitor (Hon Calvin W Hassell) for the Post Office Department carefully went over the evidence, called into the case physicians of scientific standing, and then in a memorandum to the Postmaster General recommended the issuance of a fraud order. It was issued on Aug 26, 1938 at which time the mails were closed to the Lee Products Company of Lowell, Mass.

The question naturally arises "What can be done to interfere with Nathan Peikes' continuing his quackery under the fiction of still another company?" If the past is any criterion, apparently nothing will be done except to issue another Post Office fraud order against any such company. Such penalties as closing the mails to speciously named companies that are found guilty of fraud is rather in the nature of a mild slap on the wrist.

It seems possible that more aggressive and much more effective action might be taken in this and similar instances. Sec 338 Title 18 U S Code, provides in part as follows:

Whoever having devised or intending to devise any scheme or artifice to defraud or for obtaining money or property by means of false or fraudulent pretense representations or promises shall for the purpose of executing such scheme or artifice place or cause to be placed any letter postcard package writing circular pamphlet or advertisement in any post office or station thereof or street or other letter box of the United States to be sent or delivered by mail shall be fined not more than \$1 000 or imprisoned not more than five years or both.

It is entirely reasonable to ask why the proper prosecuting authorities of the federal government cannot call the facts to

the attention of a grand jury having jurisdiction in the matter, and if indictments can be returned by it, prosecute these cases with the energy and interest it has so often displayed on other occasions. Obviously, the imposition of heavy fines, or, better yet, penitentiary sentences authorized by the section of the criminal code quoted would do much to discourage these ghoulies, and mail-order quackery would cease to be the safe and profitable business it now is. Such action would seem to be entirely in keeping with the federal government's apparent concern over the health of the people.

### SULFAPYRIDINE IN THE TREATMENT OF PNEUMONIA

*To the Editor*—In recent years many agents, chemical, physical and biologic, have been recommended for the treatment of pneumonia. In each instance the early experiences were brilliant, marked reductions in death rates and striking therapeutic responses being noted. Quinine and its derivatives, intravenous dextrose, nonspecific protein therapy, vaccines, diathermy, pneumothorax and, most recently, deuteroproteose and roentgen therapy are only a few of those which might be mentioned. In most instances the early reports considered too few cases and did not take into account the most important factors influencing the mortality in this disease. Individual cases or small groups of clinical results were reported with great enthusiasm.

The value of some of these agents even now has not been properly assessed. In most instances, however, closer scrutiny and further observations under controlled conditions have shown no particular virtues or life saving values for these various agents and they have not received wide recognition. Most of the early favorable results have been attributed to the antipyretic, counterirritant analgesic or other nonspecific effects of the particular agents used.

In the case of only one group of agents, namely type-specific antipneumococcus serums for the treatment of pneumonia due to certain types of pneumococci, have the experimental and clinical results been consistently favorable. During recent years these serums have received increasingly widespread acceptance coincident with improvements in the quality and potency of the serums produced and particularly with the recent introduction of antipneumococcus rabbit serums and improved efficiency of typing. As far as can be ascertained, all who have had the opportunity and have been willing to use good specific serums under well controlled conditions have been uniformly impressed with the striking clinical responses and with the marked reduction in mortality in the pneumonias due to the types of pneumococci for which specific serums have become available.

During the past year sulfapyridine has been introduced into the therapy of pneumonia in England, and this drug is now having a number of clinical trials in this country. The earliest clinical reports and subsequent ones from England were made without proper controls and the data presented were grossly inadequate for any evaluation. Similar reports have been made recently at various medical meetings and even greater publicity has been given this drug in the lay press and in radio reports in this country. Unfortunately no published reports have yet appeared with any data from which the value of this drug can be assessed.

Those contemplating its use or the report of results of its use will do well to heed the warning which Dr. E. K. Marshall Jr. of Johns Hopkins has recently communicated in *THE JOURNAL* (January 28, p. 352) and his pointed reference to this drug. If evaluation in experimental animals under standard and controlled conditions is difficult, it is all the more reason for extreme caution in reporting results in human beings.

Those who have spent many years in the study of pneumonia will testify to the difficulties in assessing the value of any agent in this disease before a large number of cases have been accumulated, each properly studied with respect to etiology, bacteremia and the clinical factors affecting death rates. The untoward effects and possible dangers of the remedy must also be assessed. A number of such workers are now engaged in an earnest effort to evaluate this drug, with its benefits, limitations and dangers. They are attempting to learn the proper methods of using the drug in order to obtain the optimum of benefit with the minimum of harm.

While such investigations are in progress and until the results of these studies are carefully analyzed and assessed, it is well to retain and to use the proved remedies. It would be unfortunate if the appearance of a new therapy, no matter how promising, were to cause the abandonment of agents whose curative efficacy and life-saving qualities have become established. In the case of pneumonia, sulfapyridine must still be considered as an experimental drug and, as such, should be used only under controlled conditions. There are reasons to believe that this drug will have its best effect when used in conjunction with specific serums. It is only fair to the patient ill with pneumonia that he should not be deprived of the proved value of type specific serum, when this is indicated until those in a position to undertake carefully controlled observations have had an opportunity to ascertain the value of this drug and its limitations and are prepared to present properly documented results in significant numbers of cases.

MAXWELL FINLAND, M.D., Boston

### THE PROBLEM OF THE REFUGEE PHYSICIAN

*To the Editor*—The editorial in *THE JOURNAL*, Sept. 17, 1938, concerning the problem of foreign refugee physicians in this country appears to have been sadly prophetic. Recent events in Central Europe have deprived hundreds of thousands of people of their means of livelihood and have enormously accelerated emigration. Among the expatriates coming to this country, according to the best information available there will be about two thousand doctors. The question of their fate is an important one. Will they be assets or will they be liabilities?

The fact that well qualified professional immigrants may become assets to the country is shown by previous and recent experiences. Some of our earliest universities were founded and staffed by political refugees. Within a hundred years the doctors and teachers who came here after the revolutions of 1848 have left a splendid heritage. Many of the refugee scholars and physicians who have left Central Europe within the past few years have already made important contributions to science and practice in this country. The best interests of the medical profession as a whole are served by a constant improvement in the knowledge and control of disease. Since the output of investigative work from European clinics and laboratories has been sharply curtailed, it is all the more important that the volume of scientific studies be increased here and that trained experts from abroad be given the opportunity to continue their work. In the field of general practice and in the specialties also numerous openings exist for which it is difficult to find qualified American physicians, for example, poorly paid full time positions and practices in rural communities. The farsightedness of the American medical profession and its general attitude of hospitality toward well trained foreign doctors accords well with a splendid national tradition.

There are unquestionably many difficult problems connected with finding work for refugees. One is that a certain number of them are poorly trained or of low ethical standing or still

have an arrogant attitude which makes satisfactory placement impossible. Few men so handicapped come to this country, however, as such shortcomings are an impediment to securing the sponsorship necessary for immigration. Another serious difficulty is the tendency to a concentration of large numbers of refugees in Eastern cities, already crowded with physicians, which is likely to rouse local resentment while the same number divided over a larger area would add to the efficiency of the medical community.

In the hope of safeguarding the public, avoiding injury to the medical profession and giving such help as may be possible to immigrant physicians in distress, committees have been formed in several cities. Their aims and policies are in general to raise funds for the alleviation of fundamental needs, to offer advice and opportunities for acclimatization and to arrange for a suitable distribution of refugees. Only in rarest instances will they encourage immigration. In seeking placement, their policy will be to look carefully into the credentials of foreign physicians and to recommend the qualified ones only for those positions for which no suitably trained American doctors are available, mainly in laboratories and in rural communities. A few are very distinguished for their contributions and would be an asset to any community. The placements so far effected have rarely failed to give satisfaction to all concerned. These committees hope to meet the distressing problem in accordance with American ideals and yet in as realistic a manner as possible. For this purpose, they bespeak the cooperation of the profession.

## Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

### EMERY DUSTS AND THE LUNGS

*To the Editor*—I have under my care at the present time a patient whom I believe to have pneumoconiosis due to the protracted inhalation of emery dust. As I understand it, emery consists largely of the aluminum trioxide colored with oxides of iron and manganese and therefore the disease produced by the inhalation of this abrasive dust might be expected to differ in certain respects from the more common related condition, silicosis. I have not been able to find good references in the literature to this specific condition and I am therefore taking this opportunity to ask for information. I should like to know if possible the chemical composition of the common grades of abrasive wheels, whether or not emery deposited in the lungs would be opaque to the x-rays (since aluminum itself is so pervious), whether any method of chemical analysis or microscopic examination has been devised to determine the content of emery in the sputum as an aid to diagnosis and the important biochemical differences in the reaction of the lungs to this foreign substance as compared with silica, for example. I would also appreciate any references bearing on this problem.

RALPH H. EDSON, M.D., Shelton, Conn.

*ANSWER*—Extensive exposure to any dust over long periods represented by years may induce increased pulmonary fibrosis with much increased density in hilar shadows but will not lead to a condition analogous to silicosis as found on x-ray examination or necropsy. Natural emery is an impure natural oxide of aluminum found chiefly in India, Africa, Asia Minor and the Mediterranean islands. Natural emery and corundum are rarely used at present in the manufacture of abrasive wheels. Synthetic substitutes have almost entirely replaced them. Aluminum oxide ( $Al_2O_3$ ), commonly called emery, is chiefly made by fusing bauxite, a natural aluminum ore, which may contain impurities. Carborundum, another synthetic abrasive (silicon

carbide,  $SiC$ ) is manufactured by heating in electric furnaces a mixture of coke, silica sand, sawdust and sometimes sodium silicate. These two synthetic abrasives, under various names, represent the major components of abrasive wheels in use at this time.

In forming these granular abrasives into suitable abrasive wheels, high pressures may be utilized along with binders such as clay, glue, shellac, rubber, oil, sulfur and silicates. In times past silica has been used as a binder, but this use is believed to have disappeared because of the possible dangers of silicosis. Emery is substantially pervious to the x-rays, but even though such particles were opaque the size present in the lung would preclude the ready detection of individual particles in x-ray films. Impurities in emery might pave the way for x-ray opacity, particularly if heavy accumulations were present in lymph nodes about the roots of the lungs. Much work has been carried out on chemical and microscopic methods for the determination of dust particles in the sputum. All such procedures are essentially valueless, since they establish nothing more than exposure. Fairly extensive animal work has been carried out, making use of both inhalation and injection procedures and utilizing synthetic abrasive dusts as test material. The characteristic lesion produced is one of inertness associated with foreign body reactions in contrast to the proliferative reaction from silica dust. A few important publications related to this query are listed which contain many other references. In addition, helpful materials may be obtained from the Norton Company, Worcester, Mass.

### NOSE BLOWING

*To the Editor*—What is the correct way to blow the nose? What difference does it make whether first one nostril and then the other is emptied or the two together so long as pressure is not exerted by forcible blowing?

EMILY A. PRATT, M.D., Albany, N. Y.

*ANSWER*—The correct way to blow the nose, physiologically, is to draw the secretion back to the nasopharynx and expel it. This procedure is certain to prevent any extension of infectious material to any of the uninfected cavities of the head and the ears. Nevertheless, this practice is unesthetic, and various methods have been designed from time to time to clear the nose in a more esthetic manner.

The principle, regardless of what method is used, consists of a deep inhalation through the mouth and a gentle expiratory blast through the nose. The expiratory effort through the nose can be accomplished with one or both nostrils open. It is of the utmost importance that the blowing of the nose should be extremely gentle.

For practical purposes it makes little difference what method is used as long as forcible nose blowing is at all times studiously avoided.

### CONSTIPATION AFTER STOPPING SMOKING

*To the Editor*—A woman aged 22 gave up smoking on my advice. Several days later she told me that she had become constipated since she had stopped smoking cigarettes. Where formerly she had two regular bowel movements daily it was now necessary for her to take a laxative in order to have a daily movement. She stated too that it was common knowledge among cigarette smokers that smoking did promote regular bowel movements. I am not a smoker myself so I could not confirm or deny the statement. Is there any physiologic basis for this patient's observation?

M.D., New Jersey

*ANSWER*—The observation described is not unique. But not all smokers have this experience when they cease smoking for a short time or permanently. Hence it depends essentially on some peculiarity or condition in the individual smoker. There is no evidence at present that the amount of nicotine and other substances that are absorbed into the blood from smoking has any direct or indirect action on the bowel. Nor has it been shown that the gastrocolic reflex initiated by eating and consequent digestive motility of the stomach and the small intestine is also inaugurated from the mouth and the upper respiratory passages by smoking. The most probable mechanism of the

occasional and temporary constipation on cessation of the smoking habit is temporary removal of neuromuscular tension by smoking in these people. That nervous tension may seriously interfere with the regular motility of the large bowel is well known. The large bowel is also influenced by the habits of the individual as a whole. A high strung individual accustomed to smoking after breakfast, after each meal, or when going to the toilet, may, for a while on abandoning this habit, experience temporary constipation because a conditioning factor in the favorable neuromuscular setting has suddenly dropped out. In this sense the bowel may in some persons be said to be conditioned to smoking as in others it may become conditioned to laxatives. In either case the bowel may in many cases at least be reconditioned to the absence of such factors.

#### SHORT WAVE DIATHERMY IN TONE DEAFNESS

*To the Editor*—A married man aged 29 well developed and well nourished complains of a fullness and dull throbbing sensation in both ears and mastoid regions. He gives a history of having had many middle ear infections as a boy. The drums are white and retracted and they show scars from old perforations. Roentgenograms of the mastoid regions show opacities of the peritrat cells and some of the mastoid labyrinth. Audiometer readings show a loss of 8 per cent hearing from each ear which is for conversational tones of 256, 512 and 1024 double vibration tones and a complete loss of hearing for sounds of the highest pitch. Will you kindly advise means of management? Would the use of a 6 meter Peerless short wave machine with air spaced electrodes be of value? What can you tell me of the merits of such a machine?

M D New Hampshire

*ANSWER*—Nasopharyngoscopy and eustachian catheterization to determine the patency of the eustachian tubes should be done in all such cases. Allergy should be eliminated or, if found to be present, should be controlled as adequately as possible. Increase or decrease of symptoms in the presence of head colds and sore throats should be ascertained and if either of these appears to be a contributing factor, they should receive attention. The same is true for any obstructions in the nasal cavity.

The 6 meter Peerless Short Wave Machine has been accepted by the Council on Physical Therapy but claims as to treatment of deafness have not been accepted. Short wave treatment will probably not increase the symptoms but it is doubtful that it will be beneficial.

#### ANACARDIC ACID DERMATITIS

*To the Editor*—I was questioned about the lesions that are supposed to be produced by anacardic acid. If any lesions are produced what is the description? Does it resemble rubio poisoning (I saw a case of it)? What is the preventive and curative treatment?

MICHAEL STOLFO M D Philadelphia

*ANSWER*—Anacardic acid is found in the oil from members of the cashew nut family. This oil has been found to be irritating when applied to the skin. In the West Indies it has been used for the treatment of warts and ringworm. No preventive treatment is known. Treatment is that of an acute dermatitis with mild astringent lotions, care to avoid mechanical irritation, and the like. The material should probably be avoided in the future.

#### TREATMENT OF HEMIPLEGIA

*To the Editor*—I should like information regarding reeducation of the use of hands, arms and legs following hemiplegia from cerebral embolism of cardiac origin. The embolism occurred six weeks ago and the patient has been in bed during this time. The leg has recovered enough to permit flexion at the hip and knee. There is moderate swelling of the arm and hand that of the leg having disappeared. The patient is at home and a practical nurse is in attendance. The patient is a woman 51 years of age and overweight.

M D Illinois

*ANSWER*—Recent hemiplegia will require gentle heat, gentle massage, gentle passive movements only. The heat relaxes spasm and the massage, in the form of gentle stroking with slow movements, is given to prevent adhesions. Severe spasm will require splints when treatment is not being given. Active movements are begun when the acute symptoms have subsided. The lower extremity tends to recover first, so the toes and ankle should be exercised first. Later the fingers and wrist should be exercised. The hand is the last to recover, so must be watched carefully. General exercises should be prescribed for all the muscle groups involved in the later stages of treatment. Lifting large objects, carrying different weights with both hands to straighten the elbows, shrugging the shoulders and maintaining proper posture are useful procedures. No exercise should ever be carried to the extent of tiring out the patient.

#### POISONING FROM INDELIBILE LAUNDRY INK

*To the Editor*—What is the chemical composition of indelible (laundry) ink and which constituents are most likely to act as poisons on being swallowed? A 2 year old child swallowed a small amount of laundry ink (Sanford's) and after about one hour became stuporose, cyanotic with grayish brown discoloration of the skin and almost ceased respiration. The pupils were dilated. No vomiting occurred. The urine was dark brown. It gave a negative benzidine reaction. There was no albumin and a trace of sugar was present. The blood showed no deviant from normal. Recovery followed artificial respiration and administration of oxygen.

M D New York

*ANSWER*—A typical formula for laundry ink is phenol 3 ounces, nitrobenzene 30 ounces, turpentine 12 ounces, Nigrosin 3 1/4 pounds and potassium aluminum sulfate 6 ounces. If in fact this type of ink represents the variety swallowed, the ensuing events are well accounted for. In all likelihood it is to the phenol that the chief manifestations are to be attributed. Not only by ingestion but through skin contact, some indelible marking inks may bring about injury. An instance was described in THE JOURNAL by McCord and Minster (Phenol Poisoning From Ink, Sept 13, 1924, p 843).

#### HANDWRITING AND PSYCHOLOGY

*To the Editor*—Is there any medically sound work on the correlation of handwriting and psychologic make-up?

M D New York

*ANSWER*—There is little that could be considered "medically sound" on this subject. A standard work is "Die Probleme der Graphologie," by Ludwig Klages, published by J. A. Barth, Leipzig. A journal, *Die Schrift*, is published by Rudolf M. Rohrer, Rafingasse 7, Brunn, Germany. An American publication is "Graphology and the Psychology of Handwriting," by June E. Downey, Baltimore, Warwick & York, 1919. Standard textbooks on psychiatry discuss changes in handwriting of disturbed persons.

#### UNDULANT FEVER AND MANTOUX TEST

*To the Editor*—A patient of 29 with marked loss of weight and blood positive to undulant fever shows a positive Mantoux test and a positive sputum on one test only. Does undulant fever affect the Mantoux reaction?

C C HALL, M D, Maynard Iowa

*ANSWER*—No

#### ATTACKS OF VERTIGO

*To the Editor*—In THE JOURNAL Dec 17 1936 there is a question concerning attacks of vertigo with nausea and vomiting of sudden onset and of from five to twelve days duration. From the data given by the inquirer it is impossible to make a diagnosis. I have met several of these cases in the past five years and have found most to be due to a vasomotor mechanism. In persons in whom the vertigo with nausea and vomiting due to a vasomotor cause there are found other vasomotor phenomena: coldness and at other times warmth and sweating of the fingers and some coldness of the toes also a sensation of numbness or tingling described as pins and needles by the patients and possibly a like sensation of the rim of the external ears. None have complained of headache associated with the vertigo. One of the patients had an associated diarrhea with the vertigo, nausea and vomiting. The blood pressure in all but one was found labile fluctuating from 170 to 120 within a few minutes. Some times this fluctuation is absent during the same examination but at a subsequent one will be found either much higher or lower. The diastolic pressure varies also. Just why a vasomotor instability in one person gives no such attacks of vertigo and in another does I do not know. Perhaps the labyrinth is the most vulnerable point. These have all responded with variable results to therapy of the same kind. However the same therapy in patients with vasomotor rhinitis failed completely. In my cases there was recurrence of the attacks some every few weeks, others at shorter and longer intervals before treatment was started, but during the treatment only slight vertigo, nausea and no vomiting occurred and when it did occur the intervals were as long as twenty months without an attack.

EMANUEL ROTH M D Flushing N Y

#### ATROPINE EYE DROPS

*To the Editor*—In THE JOURNAL Dec 17 1936 the question was asked about idiosyncrasy to atropine eye drops. Forty-eight years ago when I was assistant in the office of Drs. Green Post and Ewing they had for me that many patients (especially babies) were poisoned by aqueous solution of atropine which had a large area of absorption because the instillation had access to the nose and throat. Dr. Green then devised a method of dissolving the alkaloid of atropine in alcohol evaporated over a water bath and then triturating the resulting powder in pure castor oil frequently adding cocaine alkaloid which may be dissolved in the oil by trituration. The resultant solution does not go through the puncta to the canaliculi to the nose and throat but the eye absorbs the drug extremely well and naturally for a longer time. It was also found that a sensation to atropine usually exhibits only an edematous swelling of the lids with dryness and burning.

## Book Notices

**Sulfanilamide Therapy of Bacterial Infections with Special Reference to Diseases Caused by Hemolytic Streptococci Pneumococci Meningococci and Gonococci** By Ralph H. Mellon M.D. Dr. P. H. D. Sc. (Hon.) Director Institute of Pathology, The Western Pennsylvania Hospital Pittsburgh; Paul Gross M.D. Pathologist to the Institute and Frank B. Cooper M.S. Research Chemist to the Institute. Cloth Price \$4.15. 398 Springfield Illinois & Baltimore Charles C. Thomas Publisher 1938

This volume is an excellent reference work on sulfanilamide and its early clinical use. Under chemistry the authors list practically every therapeutic compound which is related to sulfanilamide and neoprontosil. The chapter on pharmacology contains frequent reference to the literature in support of the statements, increasing the value of the material presented. Experimental work, chemotherapeutic results, bacteriostatic effects and therapeutic use of the preparation are discussed. Other chapters deal with the various factors which enter into its use in therapeutics, including the cellular defenses, the fitness of the host, and natural resistance. Comparative bacteriostatic effects and the criteria of therapeutic efficiency are described. There is a bibliography of 305 references and an addendum covering the period between the time the manuscript went to press and the date of publication. This addendum includes references to photosensitization, sulfhemoglobinemia, the use of sulfanilamide in staphylococcal infections, and its relationship to the filtrable viruses, as well as consideration of the chlor of sulfanilamide incident. In view of the fact that this is one of the first books on sulfanilamide, credit is due to the authors for the careful manner in which it was prepared and the judgment used in evaluating the place of sulfanilamide in the modern therapeutic armamentarium.

**Care of Infants and Children** By Harry Lowenberg Sr. A.M. M.D. Attending Pediatrician to the Mt. Sinai Hospital Philadelphia. With an Introduction by Morris Fishbein M.D. Editor Journal of the American Medical Association. Whittlesey House Health Series. Morris Fishbein M.D. Editor. Cloth Price \$2.50. Pp. 300. New York & London Whittlesey House McGraw Hill Book Company Inc. 1938.

There is a plethora of guide books for the mother in the care of the infant. Many of these books attempt too much. They give in great detail methods for calculating feeding formulas. They enter into the discussion of diseases, giving symptoms which may only mislead the mother into attempting diagnosis and treatment. This book is limited to efforts to aid the mother and the nurse in carrying out the physician's orders, it gives such advice as will be of value to the mother in caring for the normal infant. The description of the care of the premature infant is too brief and might well be expanded. The book contains much valuable material for the mother, the nurse and the young physician. It is clearly written in concise English diction yet sufficiently detailed without being verbose. Complete directions are given when necessary to permit the mother to carry out the physician's suggestions. The first chapter is concerned with marriage and pregnancy, followed by material on feeding of infants and older children, development and hygiene, the care of the sick child, prevention of contagious diseases, and final chapters concerning sickroom preparations and the layette.

**Handbuch der Erbkrankheiten** Herausgegeben von Dr. med. Arthur Gütt. Leiter der Abteilung Volksgesundheit im Reichsministerium des Innern. Band V. Erbliden des Auges. Bearbeitet von Prof. Dr. Max Bücklers et al. Paper Price 24 marks. Pp. 310 with 221 illustrations. Leipzig Georg Thieme 1938.

This volume on hereditary diseases of the eye has been compiled by a group of physicians well qualified by experience and training to write on the subject. The facts are presented in a clear and concise form so that the practitioner as well as the specialist now has an excellent reference book on hereditary diseases of the eye—a subject of great importance in the prevention of blindness, as more than 50 per cent of the children in schools for the blind in the United States are blind because of hereditary and congenital defects. The principal purpose of the volume as claimed by the editor is to stimulate the interest of physicians in hereditary diseases of the eye. It is an authoritative compilation of our knowledge concerning these diseases, stressing particularly hereditary forms of cataract, opacities of the cornea, macular degeneration, color blindness, albinism, myopia and

other refractive errors, strabismus and nystagmus. The chapter on angiomas of the retina and coloboma of the retina are also but well illustrated. The chapter on retinitis pigmentosa is sufficiently complete to give the general physician a clear understanding of the hereditary implications. The chapter on cataract is especially complete and beautifully illustrated, furnishing the ophthalmologist and the general physician an exceptionally graphic concept of these defects.

**Internal Medicine Its Theory and Practice in Contributions by American Authors** Edited by John H. Musser B.S. M.D. F.A.C.P. Prof. of Medicine in the Tulane University of Louisiana School of Medicine New Orleans. Third edition. Cloth Price \$10. Pp. 1478 with illustrations. Philadelphia Lea & Febiger 1938.

This edition represents a complete revision from the edition of 1934. The revision includes the advances in medical science during the period and is responsible for adding 140 pages to the text. The editor calls especial attention to new sections: Haverhill fever as well as new material on influenza, undulant fever, tetanus, tularemia and a number of minor infections. There is much new material dealing with pneumonia and streptococcal infections, with the erythemas and with the advances in diagnosis and treatment of heart disease. Some new data have been added to gastroscopy and there has been complete revision of the section on the endocrine glands. An entirely new section has been written by Fuller Albright on gonadal physiology. Also there has been extensive material added on the blood diseases, on the locomotor system and on nutritional diseases. The section on diabetes has been extended to cover the use of protamine zinc insulin, and there is much new material on psychoses. Owing to the deaths of I. I. Leaman and Geo. Brown, the section on mycoses has now been entirely written by Frederic M. Hanes, and the section formerly written by Dr. Brown has been modified by E. V. Allen.

In this textbook of the practice of medicine there is special emphasis on physiology. Each of the authors in the work recognized as having been a major contributor to the topic that he discusses. The work is dependable, concrete and excellently outlined for prompt assimilation by the medical student. A brief bibliography accompanies each of the sections. If the bibliography is an indication of the extent of the revision, there are a few topics which have apparently benefited but little in a good many years. One would wish, for example, for reference to Rocky Mountain spotted fever later than 1933, since excellent contributions were published during the last two years dealing particularly with the diffusion of this disease throughout the country. It is rather sad to see the only reference to appendicitis a book written by Howard A. Kelly in 1909.

Especially useful is the section dealing with the endocrine glands. Here the references are modern, the material is highly concentrated and the data are exceedingly useful. Especially to be commended also is the section on diseases of the locomotor system, which classification includes arthritis and all the conditions affecting the bones—material frequently overlooked but poorly treated in many textbooks on the practice of medicine.

**Life and Letters of Fielding H. Garrison** By Solomon R. Kagan M.D. With an Introduction by Prof. James J. Walsh. Cloth Price \$4. Pp. 287 with portrait. Boston Massachusetts Medico-Historical Press 1938.

For every physician who knew Dr. Fielding H. Garrison and their number was legion, this will be a most welcome volume. It provides not only a brief survey of his career as a librarian, historian and teacher and bibliographer but a considerable insight into the character of the man himself as a lover of the arts, of music and of letters. Supplementary to these chapters is a collection of more than 200 pages of tributes and of correspondence which are fascinating because of the variety of the considerations, the innumerable interests and the great personalities who pass through these pages.

**Heilbrigðisskýrslur (Public Health in Iceland) 1935** Samdar af lækni eftir skýrslum beradisekna og odrum heilindum. With an English summary. Paper Pp. 218. Reykjavik Ríkisprentsmiðjan Gutenberg 1938.

At the end is a summary in English on six pages which gives a fairly good idea of the public health activities in Iceland in 1935. The population on December 31 of that year is given as 115,870. There were forty hospitals in the country with 1,091 beds, thirty-two being general hospitals with 592 beds.

**Functional Activities of the Pancreas and Liver** A Study of Objective Methods for the Estimation of Function Levels in Health and Disease By Charles W McClure MD Gastroenterologist to Fifth Medical Service Boston City Hospital Special chapters by Tage Christensen MD Resident Physician Medical Department County Hospital of Copenhagen Denmark and the late Allen W Rowe PhD With a foreword by Samuel Weiss MD FACP Cloth Price \$3.50 Pp 318 with 66 illustrations New York Medical Authors Publishing Company 1937

This interesting textbook deals with the normal physiology of the external pancreatic secretion the effects of various stimuli on the external secretory activity, the chemistry of the duodenal contents, and the clinical application of the various tests for pancreatic disease. A small chapter on achylia gastrica and its relation to pancreatic and liver diseases is included.

A second section of the book is devoted to diseases of the liver with a study of hepatic function based on duodenal contents in addition to the usual liver functional tests showing abnormal derangements of the liver. The treatment of the disturbed liver function is discussed in detail. The author chooses to use the so-called nonsurgical drainage and apparently in his hands it has given good results. However, no comparable data are offered when the magnesium sulfate is given by mouth instead of by duodenal tube, showing that the patients would probably have just as much clinical improvement. Of special interest is the section on the digestive secretion of the duodenal juice, included by one of the collaborators.

**The Social Life of Animals** By W C Allee Professor of Zoology The University of Chicago Chicago Cloth Price \$3 Pp 293 with 54 illustrations including 5 plates New York W W Norton & Company Inc 1938

Out of a wealth of personal experimentation and an exhaustive study of the work of other experimenters, an effort is made to show the relation between population and development of vital processes. The author holds that (p 51) the struggle for existence in certain brackets is mainly a matter of populations, measured only in the long run, and then by slight shifts in the ratio of births to deaths. Experiments with various forms of animal life, from protozoa to mammals indicate that a certain minimum population is essential to the most rapid development of some of the vital processes and that this development declines with a certain maximum population. He believes that this characteristic originates so low in the stage of evolution that its influence produces a law that extends up through the two main phyla of the animal world. In explanation it is suggested that association of a certain minimum number of individuals creates changes in the environment favorable to the life of group members. It is also maintained (pp 116 and 117) that "different species have different minimum populations below which the species cannot go with safety." The explanation offered for this is that when the number of individuals in any species is reduced below this minimum the number of genes necessary to adaptations to new environments and which made possible past adaptation has decreased to the point at which new adaptations cannot develop. In such a condition (p 125) there tends to be a fixation of the gene or genes that carry adaptive modifications, and evolution comes to a standstill and the species may disappear. The attempt to apply these conclusions to human society is not wholly satisfactory. Sociologists long ago learned to be fearful of biologic analogies when applied to societies consciously created. They know that the strata of the social sciences are filled with fossil philosophies built on such analogies. The author thinks that he has drawn some conclusions that are helpful in education and in the adjustment of international relations and he has undoubtedly thrown additional light on the discussions of underpopulation and overpopulation in human societies.

**Sammlung psychiatrischer und neurologischer Einzeldarstellungen** Herausgegeben von Prof Dr A Bostroem und Prof Dr J Lange Band XIII Das Realitätsbewusstsein in der Wahrnehmung und Trugwahrnehmung Von Dr med et phil Gerhard Kloss Landesmedizinalrat und erster Oberarzt der Landesheilkunst Haina/Kassel Paper Price 4.50 marks Pp 66 Leipzig Georg Thieme 1938

This is a philosophical consideration of perceptions illusions and hallucinations. It is essentially a review of the literature bringing no new concepts to light and its basis is far detached from analyses of actual clinical material. The author's manipulation of concepts is reminiscent of the methods of the old philosopher-psychologists and has little to bring to the psychology or psychopathology of living human beings.

**Public Health in Yugoslavia** By Dr A Štampar Paper Price 2s Pp 44 London University of London School of Slavonic and East European Studies 1938

At the close of the war, Yugoslavia practically started from scratch in the creation of a medical profession, medical facilities, public health and general medical service. In some districts there was only about an acre of arable land per person, one cow for three persons and one sheep for two. It was thought that the income of the population was too low to maintain any system of individual private practice. Assistance was received from the Rockefeller endowments and the Milbank Memorial Fund. A system of health centers and "health cooperatives," which would seem to be local organizations to maintain clinics and centers, was established. It is claimed that this method has brought at least some sort of medical service to large sections of the population which could not have been reached otherwise.

**Veterinary Helminthology and Entomology The Diseases of Domesticated Animals Caused by Helminth and Arthropod Parasites** By H O Monnig BA DrPhil BSc Professor of Parasitology Faculty of Veterinary Science University of Pretoria South Africa Second edition Cloth Price \$9 Pp 409 with 264 illustrations Baltimore William Wood & Company 1938

This veterinarians' textbook is written by the professor of parasitology in the University of Pretoria, South Africa and veterinary research officer at Onderstepoort. Since Africa is the continent of mammals it is also that for the mammalian parasites, and this book grew up in the paradise of parasites of the blood, the intestine and every organ of the vertebrate body. The book is not a mere rehash of older literature but a carefully wrought out account of the helminths and arthropods afflicting domesticated animals, with a clear presentation of diagnostic characters of ova larval stages and adults where known, with notes on the life cycle pathogenicity diagnosis, treatment and prophylaxis. The more important species are illustrated, often by original figures. There are introductory sections on parasitism, parasitic relations, pathogenic effects, host and organ specificity, resistance and immunity, effect of mode of life on the parasite, epizootology, geographic distribution a historical account and a host-parasite index. The historical account makes no mention of Theobald Smith's discovery in 1893 of the agency of the insect vector in the transmission of Babesia of Texas cattle fever. This edition has undergone considerable revision in the fields of therapy, pathogenicity, life cycles and nomenclature.

**Syllabus Classes for Prospective Fathers** Paper Price 15 cents Pp 14 with 3 illustrations New York Maternity Center Association [n d]

**A Talk for Prospective Fathers** By George W Kosmak MD Chairman of the Medical Board Maternity Center Association Paper Price 10 cents Pp 8 with 3 illustrations New York Maternity Center Association 1938

A syllabus with a sense of humor is this mimeographed outline for physicians' use in giving a five lesson course in prospective paternity to the heretofore unimportant parent the father. It is accompanied by a talk to prospective fathers, intended as an introduction to the course. Shrewdly reasoning that the interests of the pregnant woman will best be safeguarded if her husband understands the whole situation thoroughly, the association has prepared this course consisting of four lessons, together with demonstrations. The first lesson, to be given by a doctor from the outline furnished, deals with the process of fertilization signs and symptoms of pregnancy, the birth process the puerperium and other details, including maternity and its relationship to venereal diseases. Lesson II consists of tips to prospective fathers, with special relation to the importance of good medical care and how to recognize it. Lesson III is a demonstration session on care of the baby performed with untiring aid of 'Junior' the well known rubber doll. Lesson IV concludes with the vital technique of diapering and thus lays the groundwork for lesson V which deals with dressing the baby and making up his bed. In order that no important point may be overlooked a certificate of attendance is issued thus enabling father the forgotten man to come at last into his own. Presented half facetiously the excellent idea has been taken seriously. The outlines therefore should be revised in the interest of providing more information for those who will give the course and especially should a list be included of books and pamphlets for the expectant mother since the lecturer will surely be asked to supply such a list.

## Bureau of Legal Medicine and Legislation

### MEDICOLEGAL ABSTRACTS

#### Contraceptive Devices Statutory Prohibition of Sale, Sale Pursuant to Physician's Prescription Unlawful—

The defendants, a physician, a nurse and two social workers, were charged with violating a Massachusetts statute that prohibits the selling, lending, giving away, exhibiting or offering to sell, lend or give away any drug, medicine, instrument or article for the prevention of conception. It was admitted at the trial that two of the defendants sold and gave away articles and medicines for the prevention of conception to various patients, after the defendant physician, with the assistance of the defendant nurse, had examined those patients, and that they sold or gave away such articles and medicines only in accordance with instructions of the physician. The defendants contended that the statute under which they were convicted does not apply to drugs, medicines, instruments or articles for the prevention of conception when they are prescribed by a duly qualified physician for the preservation of life or health according to sound and generally accepted medical practices. The defendants were convicted and appealed to the Supreme Judicial Court of Massachusetts.

The terms of the Massachusetts statute, said the Supreme Judicial Court, are plain unequivocal and peremptory. They contain no exceptions. They are sweeping, absolute and devoid of ambiguity. They are directed with undeviating explicitness against the prevention of conception by any of the means specified. It would be difficult, the court thought, to select appropriate legislative words to express the thought with greater emphasis.

The statute was enacted in 1879 and was the earliest enactment in Massachusetts respecting the prevention of conception. The prevention of conception by medical advice and treatment was not unknown in 1879 and might have been the subject of an exception from the general legislative prohibition if the legislature had deemed such an exception consonant with public policy. The legislature, however, the court pointed out, had equal power to adopt the contrary view, that such an exception would endanger the effectiveness of the statute. If any exception had been intended to the broad prohibition enacted, the court thought, it would have been easy to give expression to it in the statute. To the court the inference seemed necessary that the moral and social wrongs arising from the prevention of conception appeared to the legislature so threatening in 1879, when the Massachusetts statute was enacted, that absolute and unconditional prohibition against the sale, gift or loan of contraceptive drugs, medicines or articles was necessary to meet the conditions.

The defendants relied on decisions by federal courts on somewhat similar points but no one of these decisions, the court pointed out, was persuasive to a conclusion in favor of the defendants in the present case. All of the federal cases depended in a large degree on a New York case, *People v. Sanger*, 222 N. Y. 192, 118 N. E. 637, where the governing statute contained in express terms an exception in favor of physicians, an exception lacking in the Massachusetts statute. And, in the opinion of the court, an exception could not be read into the Massachusetts statute by judicial interpretation. The statute must be interpreted and enforced as enacted and if relief is desired it must be from the law making department and not from the judicial department of the government.

The judgments of conviction were affirmed. An appeal to the Supreme Court of the United States for a review of this case was denied for want of a substantial federal question (59 Sup. Ct. 90).—*Commonwealth v. Gardner*, and three other cases (Mass.) 15 N. E. (2d) 222.

**Medical Practice Acts Injunction to Restrain Unlawful Practice**—Laman, whose only schooling in the healing art consisted of twenty two months' attendance at a chiropractic school and who had no license to practice in New York, openly and notoriously practiced medicine in that state. The attorney general and the state board of regents filed a bill in equity to

enjoin him from practicing. They alleged that his practice was a public nuisance, had caused and would cause irreparable injury to the health, safety and welfare of the people and could be abated only by the injunctive process. The trial court dismissed the bill without requiring the defendant to answer (*People ex rel. Bennett Att. Gen. v. Laman*, 295 N. Y. S. 728, abtr. J. A. M. A. 110 312 [Jan. 22] 1938), and the attorney general and those associated with him in the action appealed to the Court of Appeals of New York.

The state regulates the practice of medicine, said the Court of Appeals, not for the protection of physicians but for the protection and welfare of the people. Those seeking medical attention have no means of estimating the skill and ability of the physician and must depend on the state to permit to practice only those qualified to do so. The fact that a person who is practicing does not possess a license, however, does not mean necessarily that he is ignorant, incapable and a menace to the public health but in this case the bill alleges that the defendant is unskilled, incapable and lacking wholly in the qualifications required by statute and had endangered and would continue to endanger the public health. After discussing the medical practice act of New York, and in particular the section which imposes a criminal penalty on one practicing without a license the court stated that the question before it was whether a court of equity in New York had jurisdiction to enjoin the unlawful activities of the defendant or whether jurisdiction existed only in the criminal courts.

That a court of equity, the court continued, will not undertake the enforcement of the criminal law and will not enjoin the commission of a crime is settled beyond question. There can equally be no doubt, however, that the criminal nature of an act will not deprive equity of the jurisdiction if it would otherwise attach. Equity does not punish the perpetrator because of what he has done but it attempts to protect the rights of the party seeking relief and to prevent the performance of an act or acts that may injure many. The court pointed out that, although invasion of property rights or pecuniary interests was emphasized in some of the earlier cases as the basis for equitable interference there appeared later to be a recognition of the fact that the health, morals, safety and welfare of the community also required protection from irreparable injury. The provisions of the medical practice act were designed, the court pointed out, to protect the people from the danger of incompetent, incapable, ignorant persons. The imminence of such danger and the irreparable character of the injury are here fully apparent. The people, in the absence of special statutory authority, would not be entitled to an injunction on a showing only that the statute had been violated or that acts prohibited by the statute had been performed. The petition, however, alleges facts showing that the acts of the defendant imperiled the health of the people of the community and would continue to cause irreparable injury to the health of the people and perhaps loss of life. Enough has been shown here, if proved at the trial to warrant the issuance of an injunction.

The Court of Appeals accordingly reversed the action of the trial court dismissing the bill for an injunction and in effect ordered the case to proceed to trial.—*People ex rel. Bennett, Att. Gen. v. Laman* (N. Y.) 14 N. E. (2d) 439.

## Current Medical Literature

### AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1928 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (\*) are abstracted below.

**Apnea During Anesthesia**—Burstein and Rovenstine believe that morphine medication is a frequent factor in causing central respiratory depression with ensuing hypoxemia resulting in respiratory activity maintained by an anoxic stimulus. Further addition of an anesthetic agent enhances the central depression so that the administration of high concentrations of oxygen may produce apnea by removal of the "anoxic stimulus." To avoid such apnea during anesthesia they recommend that preanesthetic morphine be reduced when a potent nonirritating anesthetic agent like cyclopropane and excess oxygen is to be used. When such apnea does occur they suggest that a high concentration of oxygen should be maintained and artificial respiration employed until spontaneous respiration is resumed. During such apnea the use of carbon dioxide is not advised. A central respiratory stimulant such as metrazol may be useful in conjunction with oxygen therapy. When respiratory activity is maintained largely by an anoxic stimulus by way of the carotid body, treatment with oxygen is indicated to prevent cerebral damage from oxygen want.

**Gas Bacillus Infection**—Coleman and Bennett discuss the various methods of treatment that they used in their forty one cases of gas bacillus infections and the mortality. Their first seven cases were those of gas gangrene of an extremity from twenty-four to ninety-six hours in duration. Immediate amputation was performed and no persons died. Six patients with existing gas infection received serotherapy in addition to amputation. Only one death occurred. In all six cases gas bacillus infections was proved clinically and bacteriologically. Serotherapy alone was unsuccessful in three cases of gas bacillus septicemia all of which proved fatal. Postmortem examination

showed that these patients died of septicemia resulting from gas bacillus infection. In five cases diagnosed as septicemia, serotherapy and extensive debridement of the extremity were employed, but only one patient recovered after late amputation (seventh day). Roentgen treatment, used in fourteen cases, resulted in four recoveries and ten deaths. Gas bacillus infection of the abdominal wall following operation developed in three of these patients and postmortem examination showed that they had died of gas bacillus septicemia. In the four patients who responded to roentgen therapy, wide opening and amputation resulted in recovery. Two of six patients who received varied combinations of treatment (operation, serotherapy, debridement and roentgen therapy) died respectively of septicemia and of gas bacillus sepsis. The authors believe that early recognition and immediate treatment of gas bacillus infections are absolutely essential and that roentgenograms may expedite the diagnosis. Serotherapy and roentgen therapy are not determining factors unless proper surgery has been done early in the progress of the disease.

### Bovine Amniotic Fluid and Abdominal Surgery

Gepfert and Stone used a concentrated sterile fraction of bovine amniotic fluid (amfetin) in treating fifty of 100 consecutive patients having a celiotomy. The fifty presenting the most marked pathologic changes in the pelvis at the time of operation were given the amniotic fluid and the other fifty patients were used as controls. Of the treated patients 74 per cent had dense adhesions at the time of operation, while 10 per cent of the control group had similar complications. The postoperative results were encouraging in that nausea, vomiting, distention and gas pains seemed to be definitely decreased by the use of the fluid (400 cc introduced postoperatively into the peritoneal cavity). There were several subjective factors which elude evaluation. For example, it was thought that a patient who had received the amniotic fluid had a softer abdomen, expressed a desire for food earlier and as a rule was brighter than a similar control patient. It was also thought that most of the treated patients more nearly approximated normal posture when allowed out of bed. In a second series of patients, 125 control and 102 treated, analysis shows that there was 21 per cent more abdominal distention, as measured in inches, in the untreated group. During the first twenty-four postoperative hours the treated group of patients showed a 17 per cent decrease in vomiting as compared to the control patients. During the subsequent ninety-six hours the treated patients vomited only half as many times as did the control patients. Contrary to the authors' observations in the first series the treated patients showed a slight decrease of gas pains but their pains were more severe. The moderately severe attacks in the treated group, while less numerous than in the controls, were more frequent than in the first series of cases. The treated patients show some advantage as far as nausea is concerned, but again there is a discrepancy between the two groups of patients. The similarity for the average temperature and pulse rates for the two groups precludes any conclusion on these factors. Also a striking similarity was found in the preoperative and postoperative blood pressures of both groups. The average number of catheterizations in the control group exceeded those of the treated group by 22 per cent. The treated patients began voiding about six hours earlier postoperatively than did the control patients. Peristaltic sounds were heard seven hours sooner in the average treated than in the average control patient.

**Pancreatic Extract in Treatment of Gangrene**—Wolfe used pancreatic extracts in the treatment of sixty cases of diabetic and forty of nondiabetic atherosclerotic gangrene. Some of the patients have been under observation for several years. Whenever they complained of pains, leg cramps and difficulty in walking treatment with pancreatic extract was repeated. Complete healing was obtained in 75 per cent. Most of the patients were treated conservatively. The extract was administered in doses of from 1 to 3 cc either daily or on alternate days, depending on indications, in addition to an adequate diabetic regimen. Nor were other measures neglected such as proper hygiene, asepsis, short wave diathermy, low fat diets and the like. Pancreatic extract (enzyme free) seems not only to produce an early arrest of pathologic processes but to stimulate repair more rapidly and more completely than any other conservative method.

**Diagnostic Accuracy of Functional Indigestion**—In an attempt to evaluate the diagnosis of nervous indigestion, Wilbur and Mills studied the records of 354 patients who after examination at the Mayo Clinic received a diagnosis of functional or nervous indigestion or its equivalent and who were reexamined at the clinic 7.33 years later. In 303 cases organic disease was not found at the time of subsequent examination. All these patients returned to the clinic at least five years after the original examination, at which time a diagnosis of functional or nervous indigestion had been made. The results suggest a diagnostic accuracy of at least 85.6 per cent for functional dyspepsia in this series. The original diagnosis usually rested on clinical data, which included evaluation of the gastrointestinal symptoms, the frequent nervous or apprehensive nature of the patient and the negative results of laboratory and x-ray studies. There were thirty-nine cases in which organic disease of the gastrointestinal tract was found at subsequent examination. In nineteen of the thirty-nine cases a final diagnosis of duodenal ulcer was made and this represented the most common diagnostic error in the series. Other subsequent diagnoses in this group included gastric ulcer (five), cholecystic disease (three) and carcinoma of the stomach (two). This evidence suggests that when a patient gives a characteristic history of duodenal ulcer, when free hydrochloric acid is present in the gastric content and when the x-ray appearance of the duodenum is normal, care must be exercised in making a diagnosis of functional dyspepsia. Organic disease was found outside the gastrointestinal tract at the time of subsequent examination in twelve cases. It was extremely difficult to determine accurately the relationship of the diseases (pernicious anemia, cardiac disease, syphilis and others) eventually discovered to the digestive symptoms originally complained of. Gastrointestinal symptoms may occur in all the diseases diagnosed in this group but a review of the histories of these patients show only two for whom a clearcut relationship could be established between the symptoms originally complained of and the disease eventually discovered. In one case a subtotal thyroidectomy for exophthalmic goiter three years after the original diagnosis of functional dyspepsia led to complete relief of all gastrointestinal symptoms. In another instance review of the history suggests that the original digestive symptoms could have resulted from a pituitary tumor which was found to be present after a period of six years. In one case the diagnosis of pernicious anemia was made one year after the original diagnosis of functional dyspepsia. It is quite likely that pernicious anemia was present at the time of the original examination.

**Cerebrovascular Complications in Thrombo-Angitis Obliterans**—Hausner and Allen conclude, from a study of the twenty-three cases of involvement of the cerebral arteries with thrombo angitis obliterans of the extremities reported in the literature, that lesions of the cerebral vessels, while not always characteristic of thrombo angitis obliterans, may affect individuals with this disease of the extremities who do not have syphilis, hypertension, diabetes or other detectable causes for cerebrovascular lesions. They have observed eleven cases of thrombo-

angitis obliterans involving the extremities in which there was evidence of vascular lesions involving the brain. The duration of the peripheral disease in their cases varied from five months to twenty years. The ages of the patients varied from 35 to 59 years. In most of the cases the cerebral complications occurred following the onset of the peripheral disease. The cerebral lesion preceded the peripheral symptoms in only three cases. In these three cases the hemiplegia was present two, one and four years respectively before the onset of the peripheral symptoms. Thrombo angitis obliterans must therefore be suspected in cases of cerebrovascular disease of obscure etiology. The main neurologic symptom was hemiplegia, which occurred transiently, once or several times or permanently. In some cases there was confusion, disorientation, aphasia and loss of memory, symptoms which frequently cleared up entirely. Hemianopia, present in two cases, disappeared in one case following sympathectomy. The symptoms of thrombo angitis in the brain depend chiefly on where the lesion is located in the brain. The eleven patients with cerebral involvement were from a group of 500 with thrombo-angitis obliterans of the extremities. It may be found that this complication occurs more frequently if attention is directed to it. The study emphasizes that cerebrovascular complications may occur in cases of thrombo-angitis obliterans and may precede evidence of the thrombo-angitis obliterans of the extremities. It is also apparent that peripheral thrombo angitis obliterans may be the least serious part of a disease which may be disabling or may terminate life as a result of cerebral or cardiac involvement.

**Subdural Hematoma**—In the neurosurgical service of the Johns Hopkins Hospital between 1914 and 1935 Kunkel and Dandy encountered forty-eight cases of subdural hematoma in which the lesions at operation were found to have the characteristics of the traumatic hematomas. Of the forty eight patients forty were adults, six were minors and two were infants each 9 months of age. The largest number of hematomas (eleven) occurred in the sixth decade of life and the smallest number (three) occurred in the first decade. Five occurred in the second decade. The average age for the entire group was 41.2 years. There were forty-three male and five female patients, a disproportion encountered in all other case reports and doubtless correctly attributed to the accepted cause, trauma. Since an unlocalized tumor of the brain is suspected in a high percentage of cases of subdural hematoma, the localization of the lesion is ultimately dependent on ventriculographic examination or its equivalent, direct puncture of the hematoma. A subdural hematoma can not escape detection by ventriculographic study and not infrequently the exact character of the lesion can be determined from the ventriculograms alone. The only treatment is surgical. Although repeated aspirations of a subdural hematoma have been advocated, the authors experience with one hematoma so treated was the least satisfactory of the series, the patient recovered completely but required repeated tapings for three

months. Their plan of attack in recent years has been to turn down a very small bone flap, excise with the electrocautery the outer membrane flush with the dural incision and strip the thin, avascular and unattached inner membrane as far as possible from the surface of the brain. They irrigate the hematoma from the cranial chamber by flushing with Ringer's solution. Frequently one or more isolated pockets of blood exist in the subdural space. Careful inspection of this space will disclose them bulging into the large primary cavity. They are punctured, evacuated and irrigated, it has not been necessary to remove any of their covering membranes. Whether or not removal of the inner and outer membranes is necessary cannot be stated. The authors have gradually lessened the size of the cranial exposure and have seen no difference in the immediate or ultimate results. Among the forty-eight patients there were fifty hematomas. Forty-six patients recovered and two died. Subsequent reports from the patients who recovered have been gratifying. Twenty-eight were known to be in normal health in 1937 and among these are two who were operated on twenty years ago. No replies were received from twelve patients, and six are known to have died from causes unrelated to the hematoma a considerable time after their discharge from the hospital.

**Mesenteric Lymphadenitis**—According to Foster, mesenteric lymphadenitis is a little understood disease that cannot always be diagnosed alone but must not be considered unimportant because of this. Vague abdominal symptoms not apparently caused by any definite disease of any particular organ should draw the physician's attention to the mesenteric lymph nodes, if only because of the intimate association between the mesenteric nerve plexus, the mesenteric arteries and veins and the mesenteric lymph nodes themselves. The mesenteric lymphatics are not sufficiently emphasized as to their functional importance both in health and in disease. Appendectomy is the treatment for mesenteric lymphadenitis, it should be performed as soon as the diagnosis is made. Indications of other intra abdominal disease do not furnish any excuse for neglecting the appendix. Other pathologic conditions of the abdomen should likewise indicate the need of surgical intervention in addition to appendectomy, when necessary. Infection involving lymph nodes in any part of the body (especially the neck) should remind the examiner of the many mesenteric nodes which also may be infected. The vermiform appendix becomes more important than ever before because of the high percentage of diseased appendices observed in a total series of 147 cases of mesenteric lymphadenitis (in all but two of which the diagnosis was proved) from the records of the New York Post-Graduate Medical School and Hospital, Columbia University.

**Splenectomy and Bacterial Endocarditis**—A case of proved subacute bacterial endocarditis in which the condition was treated by splenectomy is reported by Polowe in detail. The patient is alive and well more than twenty months after splenectomy. An analysis of the fifteen cases thus far reported in which splenectomy was tried in an effort to alter the course of subacute bacterial endocarditis shows that in only three was the diagnosis proved prior to operation. These three patients died within fifteen weeks after splenectomy. It appears, then, to the author that his case is the first proved case of subacute bacterial endocarditis in which the patient recovered after splenectomy. He believes that when subacute bacterial endocarditis manifests progressive secondary anemia associated with splenomegaly and pain in the left side of the hypochondrium splenectomy is of definite palliative value. Splenectomy appears to act as a substitute for transfusions. It arrests the progress of the anemia and produces ultimate improvement in the hemoglobin and erythrocyte content of the blood. The white blood cell content is increased and in cases in which the condition is associated with thrombocytopenia the platelet count is lifted to normal levels. Abdominal and articular pains disappear after splenectomy and a quieting effect on the action of the heart is observed. The author believes that the spleen is a continuous source of reinfection and of absorption of bacterial toxins. In his two cases the patients' chief complaint abdominal pain was entirely relieved. The first patient died fifteen weeks later of cerebral embolus. The second patient, as stated, is alive and well more than twenty months later.

**Estrogenic Therapy of Menopausal Disorders**—Schneider points out that careful analysis frequently reveals various combinations of menopausal symptoms with complete absence of hot flashes in many cases in which estrogenic therapy is indicated. The variations of therapeutic requirements explain the failure of routine methods in treating menopausal disorders. Three types of reaction following parenteral administration of estrogen have been found of value in establishing the diagnosis and in determining the dosage in each case. These reactions occur within one hour after intramuscular injection and are of considerable significance even though transitory. 1 Total absence of reaction usually indicates that estrogenic deficiency exists and that the initial dosage has been inadequate and should be increased. 2 Improvement or relief of symptoms and a feeling of well being is evidence that an actual estrogenic deficiency exists and that treatment should be continued. 3 If extreme exhaustion, pain in the ovarian regions or bearing down sensations are transitory and followed by relief of the original symptoms estrogenic deficiency exists but this shows that the initial dosage was excessive and should be decreased. If these symptoms are prolonged and not followed by relief of the original symptoms, estrogenic deficiency does not exist and treatment should be discontinued. If subjective symptoms are used as a criterion for treatment, estrogen will be administered only to women having an estrogenic deficiency, while massive doses administered to women having normal ovarian function might result in abnormal tissue growth and the production of carcinoma. The author believes that an analogous situation is that of the relationship of x-rays and radium to carcinoma.

**Hypothyroidism and Psychosis**—Although the diagnosis of psychosis with myxedema is rare, three cases have been observed at the Elgin State Hospital during the last few years. Simon reports these cases in order to emphasize some of the factors which may modify or determine the reaction pattern and course of the psychosis. The variations in their reaction patterns are attributed to differences in the hereditary, constitutional and environmental background as well as organic conditions. The author believes that young persons in whom myxedema develops and who possess a schizoid personality are prone to develop schizophrenic psychoses. In elderly patients with involutional and cerebral arteriosclerotic changes an organic psychosis characterized by a loosely constructed paranoid delusional system with confusion and vague hallucinatory experiences is apt to develop. Appropriate thyroid therapy may improve the physical and possibly ameliorate the mental condition.

**Virus from Ticks Causing Human Infection**—Dyer states that a newly recognized agent recovered from ticks (in Montana) has been found capable of causing infection in man. The relationship of this infection to Q fever of Australia is suggested by cross immunity tests in guinea pigs. That the two diseases may not be identical is indicated by failure to infect four monkeys, while the Australian workers report that monkeys are susceptible to Q fever. Epidemiologically the latter disease has been found in Australia, particularly among workers in abattoirs and among dairy farmers. Such an epidemiologic picture is not at variance with the picture of a "tick borne infection, since it suggests a reservoir in animals and the existence of the infection in their arthropod parasites.

**Blood Studies in Obstetric Patients**—Eskridge and Serwer found that during the first trimester of pregnancy 53.8 per cent of their 1,000 patients showed an erythrocyte count of 4 million cells or above, and 46.2 per cent had an erythrocyte count below 4 million. This increased during the second trimester to 55.9 and 44.1 per cent respectively. A decrease was observed during the third trimester, with 46.9 per cent having an erythrocyte count above 4 million and 53.1 per cent below 4 million. A hemoglobin of from 11.9 to 15.3 Gm (the so called average group) was present in 84.2 per cent of the patients in

the first trimester, which remained at 84.5 per cent during the second trimester and decreased to 52 per cent during the third trimester. The group of patients having 15.3 Gm of hemoglobin and above showed only 0.7 per cent change throughout the entire course of pregnancy, despite the fact that the greatest drain by the fetus on the mother is at its height during the third trimester. The authors did not observe any appreciable change in the leukocyte count throughout the course of pregnancy, with one exception, in which there was a slight gradual increase in the percentage of patients who had a leukocyte count above 10,000 during the third trimester. The marked rise which many authors speak of as labor approaches was absent in the series. The predominant granulocyte percentage was between 70 and 80 during the first trimester, and between 70 and 90 during the second and third trimesters. The reverse order was true of the nongranulocytes. During the third trimester, 80.9 per cent had a bleeding time of less than three minutes, the maximum being six minutes. 76 per cent had a coagulation time of less than three minutes during the third trimester, the maximum being 8.5 minutes. A total of 3,000 basal metabolic rate estimations were done, of which 1,952 were within the normal range (plus 10 to minus 10), 220 were above normal and 719 were below normal. There was no appreciable change in distribution as pregnancy progressed, there being only a slight increase in the number of normal range during the second trimester and a further slight increase during the third trimester. A small progressive decrease in the minus group was also observed during the later trimesters. There was an increase in the later trimesters on the plus side as pregnancy progressed.

**Therapeutic Use of Helium**—Metz and his associates have used helium in emphysema, bronchiectasis, pulmonary fibrosis and other conditions obstructive to breathing. Their results have been as satisfactory as those of other workers in the field. However, they emphasize that the administration of helium is dangerous when given by incompetent or untrained persons. The administrator must be well acquainted with the closed circuit system and the physiologic principles involved. Improper administration of helium may not only be valueless but may jeopardize the life of the patient by asphyxia. To be effective, nitrogen must be rigidly excluded because it defeats the purpose of the helium by increasing the weight of the mixture. Care must be taken to supply sufficient oxygen continually for metabolic needs. When a closed circuit is used positive pressure should be applied to the rebreathing bag during inspirations so that the patient is not compelled to breathe against the resistance in the circuit. Gentle positive pressure during inspiration not only renders breathing easier but aids the gas mixture in penetrating alveoli which have become more or less blocked by mucus and by bronchial spasm. The authors have also verified the results of Barach on the uselessness of helium in asthma, which is controllable by epinephrine. When administered during an attack in these cases, the cyanosis disappears and breathing becomes somewhat less difficult but the duration and frequency of the attacks are in no way altered. In borderline cases in which the patient is partially refractory to epinephrine, the administration of helium will again restore the effectiveness of the drug, after which the gas is of no further value. The authors believe that the present known uses of helium in the field of medicine are only suggestions of its possibilities and that further study and experimentation will bring to light many more conditions in which its use is beneficial.

**Sympathectomy in Cutaneous Diseases**—Telford performed sympathectomy in the treatment of a number of these patients suffering from sclerodactyly, but the results were on the whole disappointing. No permanent benefit has been shown in the more severe cases with gross contracture and ulceration. Immediately after the operation pain has been abolished in dramatic fashion, but in all cases it has returned. One woman was enabled to return to her work as a weaver. While engaged in the study of sclerodactyly the author attempted the treatment of various other types of cutaneous and subcutaneous sclerosis. In the patchy and superficial form of scleroderma, sympathectomy has checked the progress of the disease and in some cases has brought about much improvement in the local condition. In the severe sclerosis occasionally seen in the limbs of infants, a condition apparently due to a fibrous dystrophy of subcutaneous fat the operation has been without success. In three cases of hyperhidrosis, sympathectomy has abolished the sweating. The results for twenty-seven patients with anterior poliomyelitis and forty with the erythrocytosis-Bazin syndrome who have been operated on by lumbar sympathectomy have been excellent especially for the younger patients. In a few of the older patients and in the more obese legs improvement has lapsed after two years. Although sympathectomy will lead to a dramatic healing of "trophic" ulcers their subsequent history may be disappointing owing to the ceaseless care necessary to prevent trauma to the insensative area. Sympathectomy is still on trial but because of the results that the author obtained in the varied instances he believes that it may prove of lasting benefit in certain selected cases of disease of the cutaneous and subcutaneous tissue.

\*Immediate Feeding in Hematemesis and Melena Review After Twelve Months Trial J D Herlihy—p 996

**Immediate Feeding in Hematemesis and Melena**—For more than twelve months Herlihy has employed Witts's modified Meulengracht routine of immediate feeding in hemorrhages from peptic ulcer. He believes that this method combines the best features of the Meulengracht and the Sippy methods and fulfils all the other requirements of treatment. His results to date in the treatment of both private and hospital patients have been distinctly encouraging. So far there has been no occasion to invoke the aid of the surgeon. Should this need arise, the surgeon would be offered a reasonably good risk and not a forlorn hope as in the past. Since solitary hemorrhages are rarely fatal (in about 4 per cent) and with recurrence the mortality rate rises to 40 per cent (with further hemorrhages to 60 per cent), the key to the situation is to prevent such happenings. The treatment, in short, should be as follows: 1 Morphine should be used only when anxiety is a prominent feature. 2 Blood transfusion should not be regarded purely as a preparatory measure for surgical intervention. Medical treatment will improve by its adoption. It is not employed as a routine measure but should be if an analysis of the blood indicates it. It is essential to treat the general condition of the patient and not to concentrate on one symptom alone. After blood transfusion a rise in the hemoglobin percentage occurs. Thus is eliminated the state of anoxemia and a condition is created which directly aids healing and must therefore tend to prevent a recurrence of bleeding. Should further hemorrhages occur, the blood transfusion should be repeated as often as is necessary, preferably by the continuous drip method. 3 With a hemorrhage and its associated vomiting and the like, the patient probably loses between 2,000 and 3,000 cc of body fluid. As the normal water requirements of a patient are 3,500 cc a day, it is evident that he requires about 6,000 cc during the first twenty-four hours. This should be followed each subsequent day, with 3,500 cc. The rigid withholding of food by mouth is a further distinct fault, as a patient in danger of dying from exhaustion must be provided with a diet containing sufficient calories and vitamins, and to allow a stomach to remain empty and exposed to the unbuffered gastric juices is incorrect treatment of peptic ulceration. Excessive movements of the stomach are enhanced by hunger. The food must be kept moving through the stomach in order to rest it. The patients that the author treated so far have received from 2,500 to 3,500 calories daily and a total fluid intake of at least 2,500 cc. In addition, they were allowed water or dextrose solution between meals. The milk that they were given was not citrated but, if desired, was flavored with malt preparations. Alkaline powder and belladonna were seldom found necessary but were given in the usual manner when required. Vitamins were provided in the form of an autolyzed yeast preparation, orange and tomato juice, cod liver oil and malt. These were given at first in full doses to overcome any possible storage deficiency especially of vitamin C. According to the progress made and when it was certain that bleeding had ceased, the gradual transfer to a modified Sippy diet followed.

Capillary Bronchitis of Diphtheric Origin and Secondary Otitis Due to *Loeffler's Bacillus*—*J. M. Paez de la Torre*—p. 803

**Urinary Colibacillosis in Nurslings**—*Ribadeau-Dumas and Chabrun* say that, however frequent may be the urinary infections provoked in nurslings by the colibacillus, they are usually benign. As a rule, the colibacillary pyelonephritides of young infants are cured easily by suitable alimentation and by urinary antiseptics. Nevertheless, grave forms of colibacillosis also are observed in infants. The existence of a congenital malformation in the urinary tract such as stenosis of the ureter or a vesical malformation may be an important factor in the grave forms. There are also serious forms of pyelonephritis, in which anatomic malformations are absent and in which the grave aspects may be due either to the special quality of certain strains of colon bacilli or to peculiar microbial associations. The authors report three cases. The first one concerns a nursing aged 5 months, in whom colibacillosis became manifest in severe nervous disturbances. At the onset the fever, the muscular rigidity and the convulsions simulated a meningitis. A little later a veritable catatonic syndrome appeared, which was characterized by muscular rigidity, coldness, a suspension of spontaneous motions and the prolonged persistence of passive attitudes (catalepsy). These symptoms were accompanied by dyspnea and vasomotor disturbances. Finally, in the course of a relapse there appeared a cerebellar syndrome, that is disturbances in the equilibrium, tremor and dysmetria. In attempting to explain the neurologic symptomatology of the colibacillary infection the authors direct attention to studies by Vincent, who demonstrated that the colon bacillus produces two types of toxins: an endotoxin which is enterotropic and hepatotropic and an exotoxin which is neurotropic. The production and toxicity of the latter toxin varies in different strains of the colon bacillus. By the injection of this toxin into rabbits, Vincent was able to elicit various nervous disturbances: coma, paralysis and retropulsion. The authors further mention Baruk and Claude, who demonstrated that the neurotropic toxin of the colon bacillus produces catatonics in cats, mice, guinea pigs and pigeons. In view of these observations, the colon bacilli obtained from the aforementioned nursing were tested in a rabbit and it was found that the rabbit developed paresis of the neck and of the posterior members and also diarrhea and dyspnea. The second case of grave colibacillosis described by the authors concerns an infant of 4½ months. In this case a typical urinary colibacillosis became complicated by an acute nephritis, which became evident in albuminuria, edemas, azotemia and acidosis. Then hypertrophy of the kidney developed and the necropsy disclosed a massive thrombosis of the renal vein. The third case concerned a child of 6 months. This child developed a bronchopneumonia, which was soon followed by a urinary bacillosis which was accompanied by severe nervous symptoms. The examination of the urine disclosed colon bacilli and staphylococci. The necropsy revealed in addition to the lesions of pyelonephritis a pulmonary abscess with staphylococci and a double otomastoiditis with pneumococci. The link which unites these disparate forms is the presence in the urine of pus and colon bacilli.

**Treatment of Lymphangiomas with Sclerosing Injections**—*Fonseca e Castro* says that the treatment of angiomas and lymphangiomas by means of injections is not new. The employment of coagulating substances was quickly abandoned, but the use of sclerosing substances is of greater interest. To be sure several have fallen quickly into disuse, such as tincture of iodine, oil of turpentine, mercuric iodide and salts of magnesium. Others, however, have been used widely: sodium salicylate, quinine-urethane or quinine-urea and finally sodium citrate. This last substance is the least irritating of all. Although possessed of the same sclerosing action as the others, it is practically harmless, because it does not have a necrosing action if it is injected in reasonable quantities. That is why Sicard prefers it for the treatment of varices and Trousier utilizes it in the therapy of certain forms of arteritis. The author found it to be a satisfactory means to obtain reduction by sclerosis of

tuberous angiomas. He developed the technique and the indications for this treatment in observations on dozens of patients. He employs a saturated solution of sodium citrate, which he injects deep into the tumor, if it is voluminous, he makes two or three punctures at different sites. Not more than 1 cc. is injected into each puncture and usually the quantity is less (0.5 cc.). Before the injection is renewed all reactions provoked by the previous one must have entirely disappeared. The technical regulations of the treatment of angiomas by injections of sodium citrate were applied also in several cases of lymphangioma and the author found that in these cases the results were even superior to those obtained in the majority of cases of angioma. He describes the clinical histories of three such cases. The first patient, a child aged 15 days, had a lymphangioma the size of a small orange, in the right supraclavicular region. Injections of sodium citrate were continued over a period of two months. At the end of that period the lymphangioma had completely disappeared and today, nine years later, there is no sign of a tumor. The second patient, a child aged 18 months, had a voluminous lymphangioma in the right axillary region and the third patient was a child of 20 days with a large lymphangioma in the left cervical region. In all these cases the injections of sodium citrate reduced the lymphangiomas to such an extent that they may be regarded as cured. The number of injections varies in the different cases.

**Influence of Quinine on Labyrinth**—*Chrysos and Yanouli* point out that in Greece quinine tablets are often used by persons who want to commit suicide. This is due to the fact that, because of the wide spread of malaria, quinine is easily obtainable. The authors studied the effect of large doses of quinine on the labyrinth in twenty eight cases, in twenty five the labyrinth was studied during life and in three anatomopathologic studies were made. Ten of the patients presented nothing of interest as far as the ear was concerned. Of a number of those who did present otic symptoms, the authors give clinical histories. These histories indicate that the patients had ingested from 5 to 10 Gm. of quinine. The extension of the lesions provoked by the absorption of quinine depends partly on the quantity of the alkaloid that has been taken and partly on the resistance of the organism. Evidently the time of day and the quantity of food taken before the absorption of the medicament as well as the presence or absence of vomiting and the length of time which elapsed before its onset, are of great importance. In some of their patients the authors observed congestion of the tympanum, a symptom which had been described previously by Rose. In one case they noted an exacerbation of a chronic otitis. Nearly all their patients complained of buzzing in the ears, which is a sign of labyrinthine congestion. After citing opinions expressed by Wittmaack, Beck, Schwabach and others on the action of quinine on the ear, the authors say that in two of their patients they observed vasomotor disturbances of the labyrinth, namely periodic attacks of vertigo and instability, which persisted for a long time. However, the authors do not consider quinine the principal cause of these disturbances because some other factors seemed involved in the two cases. They point out that although Haug regarded quinine intoxication as a principal cause of hyperacusis they never observed this condition. Other observers noted blindness and deafness as a complication, but the authors never detected deafness and in only one case did they note a considerable diminution in visual acuity. In several cases they observed reactions of the vestibular labyrinth, such as nystagmus of the first or second degree, deviation of the hand and sideward falling. In the excitation of the labyrinth with caloric and galvanic tests they noted a diminution in its excitability, whereas other investigators observed an augmentation in the excitability of the labyrinth, probably because small doses of quinine provoke a congestion of the auditory organ and consequently a hyper excitability.

**Diastase Reaction for Diagnosis of Pancreatic Disorders**—Kapp and Vischer say that the diastase test for the diagnosis of pancreatic disorders, which was introduced by Wohlgemuth, has been evaluated differently. Whereas some recommend this method, others reject it. The authors investigated the method in the material of the medical and surgical clinic of the university of Basel. Tests in thirty-five cases in which either operation or necropsy had demonstrated a pancreatic disease revealed normal diastase values of the serum in 54 per cent of the cases. In only 46 per cent of the cases did the diastase test support the diagnosis. In the presence of tumors the increased values were detected more frequently than in cases of acute pancreatitis. In the latter disorder the failures of the diastase test were especially frequent. In twenty-six cases in which the clinical aspects as well as the outcome of several tests (condition of feces after Schmidt's test meal and positive ether reflex according to Katsch) indicated pancreatic disease, the diastase values in the serum showed a similar behavior to that in the cases that had been verified by operation or necropsy. To be sure the percentage of cases with normal values was somewhat lower, 42, compared to 54 in the verified group. The authors give their attention further to ninety-five cases in which, although increased diastase values existed in the serum, the clinical signs indicated extrapancreatic rather than pancreatic disorders. In the majority of these cases, that is in sixty-six, there existed gastric intestinal or biliary disorders, in thirteen cases diabetes and the remaining number of patients had various disorders such as cardiac insufficiency, intoxication, hemolytic icterus and septic diseases. Summarizing the results of their studies the authors say that only about 50 per cent of the cases, in which pancreatic disorders are certain, show increased diastase values in the serum. Thus the normal outcome of the diastase test cannot be regarded as a definite proof of the absence of pancreatic impairment. When other pancreatic tests indicate a lesion of the pancreas, the diastase test should be made as a corroborating test. Even if there are no clinical signs of pancreatic disease increased diastase values indicate at least an involvement of the pancreas. The observations discussed here concern the diastase content of the serum, because this has been regarded as more reliable than the test on the urine. In some cases in which pancreatic disorders seemed probable and in which serum and urine were tested, greatly increased diastase values were found in the urine whereas the serum values were normal but the reverse condition was also found in many cases. The lack of uniformity in the outcome of the diastase test induced the authors to investigate in healthy persons the relationship between the serum and urine values under the influence of various diets. They admit that the small number of tests does not permit the formulation of new theories, but the experiments do prove that the conditions under which the tests are made must be known. It was found that increased diastase values in the urine may be the result of the food intake. Moreover, it is suggested that the diastase test might gain in importance if it is further developed, that is, if attention is given to the time and quantity factors in connection with the tolerance tests.

- \*Alcohol as Possible Vehicle of Gas Gangrene Infection G Benzoni—  
 p 1107

**Alcohol in Transmission of Gas Gangrene**—Benzoni says that in hospitals and similar centers it is customary to keep syringes and needles which are used for administration of hypodermic injections and hypodermoclysis in alcohol as a disinfectant.

As a rule alcohol in the jars in which the instruments are kept is changed once a day. The author searched for the presence of *Bacillus perfringens* on different specimens of alcohol taken by sterile means either from the jars in which the syringes and needles were kept or from the bottles from which the jars were supplied. He used a method of precipitation of a sediment in alcohol to which 1 or 2 cc of a sterile serum was added. Cultures from the centrifuged sediment were prepared by Zeiler's method. Thirteen of eighteen specimens taken from the jars were turbid and contained *Bacillus perfringens*, as verified by cultural and biologic studies. Five specimens from the jars and six from the bottles were clear and did not contain the bacilli. The author therefore concludes that ethylic and denatured alcohol is a vehicle for *Bacillus perfringens*. It has no bactericidal properties against gas gangrene even if in contact for a long time. There is the possibility of transmitting gas gangrene infection by means of the needles or syringes in the course of the administration of hypodermic injections or hypodermoclysis. It is advisable to take the instruments out of the jars by means of sterile forceps, never letting the fingers come in contact with the alcohol which is used as a disinfectant, to change the alcohol in the jars more frequently than is generally done and, if possible, to seek another disinfectant which may have more effective bactericidal action against gas gangrene than alcohol.

**Gold Therapy and Vitamin C**—Sande observed three patients who did not tolerate gold therapy. One had bloody sputum, another one had petechiae and the third one developed hepatic symptoms with severe urobilinogenuria. These disorders did not yield to the customary treatments. Sande cites others who made similar observations in the course of gold therapy and then points out that Piesocki and Danow obtained favorable results with vitamin C in cases of intolerance to arsphenamine and to gold therapy. These results and those obtained by Hasselbach and others in the treatment of tuberculous hemoptysis induced Sande to try vitamin C for the patients who did not tolerate gold therapy. He administered from 100 to 200 mg of vitamin C by intravenous injection and found that the petechiae, the blood in the sputum and the urobilinogenuria disappeared. He further describes experiments on guinea pigs. The animals were treated with different types of gold preparations and then the vitamin C content of the various organs was determined. It was found to be greatly reduced in all organs except the liver in which it remained fairly constant. The reduction was greatest when the gold preparations were administered intravenously. The author concludes that the favorable results obtained in the patients and the observations in the course of the animal experiments justify the prophylactic and therapeutic application of vitamin C in the course of gold therapy.

**Erythrocyte Sedimentation Speed in Tonsillectomy**

Kotzka studied the sedimentation speed of the erythrocytes in 200 patients who underwent tonsillectomy. He employed Westergren's method for all tests and found that 80 per cent of the patients had a normal sedimentation speed before the tonsillectomy. Tests made immediately after the intervention revealed that a noticeable change in the sedimentation speed becomes evident only after at least twelve hours has elapsed. In the days following it increases. On the third day, when the inflammatory manifestations in the tonsillar bed are most pronounced the acceleration in the sedimentation is usually greatest. After that the values gradually subside. This course is usually observed in patients who merely had a chronic tonsillitis without local or

general complications. In cases of rheumatism and nephritis, however, the postoperative fluctuations in the sedimentation speed are greater, particularly when the sedimentation speed was already increased before the intervention. The return of the sedimentation rate to low values often required three months and longer, especially when the tonsillectomy was followed by an exacerbation in the articular and renal inflammations. A final evaluation of the therapeutic effect of tonsillectomy is possible only after prolonged observation. In 123 cases, control tests could be made after the intervention of from one to five months. These tests revealed that tonsillectomy was followed by an absolute reduction in the sedimentation speed in seventy-eight of the 123 cases (63.41 per cent), by an absolute increase in twenty-six cases (21.14 per cent) and by unchanged values in nineteen cases (15.45 per cent). The author reaches the conclusion that in connection with tonsillectomy the systematic control of the sedimentation speed of the erythrocytes is of great diagnostic and prognostic value. He recommends that the sedimentation speed be determined before and at monthly intervals after the operation. If after one or two months the tests show an absolute reduction, he regards this as an indication that the tonsillectomy has removed the focus of the disease and that the patient's general condition is improved. If this status has not been attained after two or three months, it must be assumed that either the complications (endocarditis or articular rheumatism) cannot be influenced by the tonsillectomy or the result has been obtained but is masked by other diseases such as tuberculosis and empyema of the sinuses.

**Liver as Defense Organ in Bacterial Infections**—Reiss injected into the blood stream of eight rabbits such quantities of bacilli that the bacteria could be demonstrated in the microscopic examination of sections of the organs. One each of the first four rabbits had been immunized respectively against *Bacillus pyocyaneus*, *Bacillus albidigenes*, the pseudodiphtheria bacillus and a gram-positive bacillus that had been cultured from earth. Into the other four nonimmunized rabbits the same number of the respective bacteria were injected. Five minutes after the injection had been completed the animals were killed and the organs were examined under the microscope either at once or after twenty-four hours of incubation. It was immediately evident that the examined organs—liver, spleen, adrenals and brain—did not contain the same number of bacteria per unit of volume. The liver was overloaded with them, whereas in the other organs they were detected comparatively rarely. A mechanical filtration in the capillaries cannot have been responsible for this, because the bacteria, which were injected into the jugular vein, were carried to the right auricle, the right ventricle and from there to the lungs after passing the pulmonary capillaries they were carried back to the left side of the heart and from there into the general circulation. No phagocytosis could be observed in the phagocytic cells of the kidneys, adrenals, brain and spleen. To be sure, this does not exclude the possibility of a slight phagocytosis here. However, Kupffer's cells in the liver were practically filled with bacteria. Kupffer's star-shaped cells contained even more bacteria in the immunized animals than they did in the nonimmunized animals. After citing other differences between the immunized and the nonimmunized animals, the author stresses that these observations permit the conclusion that the reticulo endothelial system in its entirety does not participate uniformly in the destruction of the agents of bacterial infection but that the liver plays by far the most important part in defense against the pathogenic micro-organisms.

Connection Between Primary Chronic Polyarthrits with Achlorhydria and Anemia R. K. W. Kuipers—p. 5725

\*Treatment of Warts P. J. van Putte—p. 5737

Aimed Roentgenography of Lungs A. Draen—p. 5743

Treatment of Psoriasis T. M. van Leeuwen—p. 5750

**Polyarthrits, Achlorhydria and Anemia**—The fact that a number of authors reported the existence of an achlorhydria in primary chronic polyarthrits induced Kuipers to investigate the concurrence of these disorders in sixty-five cases. After withdrawing a specimen of gastric contents from the fasting stomach, he gave the patients 250 cc of unsweetened tea. After that specimens were withdrawn at fifteen minute intervals. If at the end of forty-five minutes the specimens contained no free hydrochloric acid a subcutaneous injection of 0.5 cc of histamine was given. After that a specimen of gastric juice was withdrawn at hourly intervals. In thirty-four (52 per cent) of the cases achlorhydria was observed after the tea test, and in fifteen (23 per cent) the achlorhydria persisted after the histamine injection. Comparing this incidence with that in healthy subjects, the author finds that in patients with primary chronic polyarthrits the percentage of achlorhydria is greater. He observed also that this achlorhydria is related neither to the age of the patient nor to the duration of the illness. Further he takes up the question whether the achlorhydria is related to the hypochromic anemia which he so frequently encountered in his patients with primary chronic polyarthrits. He found that achlorhydria is just as frequent in patients with severe anemia as in those with a normal hemoglobin content and that, on the other hand, anemia is found in patients with normal gastric secretion as well as in patients with achlorhydria. From this he concludes that the hypochromic anemia is not caused by the achlorhydria and thus has no connection with the disordered gastric function. To be sure it is possible that the impaired iron resorption in achlorhydria increases the severity of the existing anemia, but the table recording the author's observations does not indicate this definitely. Another factor, which indicates that the achlorhydria is not connected with the hypochromic anemia, is that anemia responds to gold therapy and the achlorhydria does not.

**Treatment of Warts**—Under the term warts, van Putte combines the verrucae vulgares, the verrucae planae juveniles and the condylomata acuminata and states that it is generally assumed that these three forms of warts are caused by the same ultravirus. After citing some of the experiments on which the theory of the ultravirus etiology of warts has been based, the author says that there is as much disagreement about the therapy of warts as there is agreement about their etiology. He cites a number of treatments he found recommended in the literature on warts and then describes the method which he regards as most satisfactory. In the case of verrucae vulgares he disinfects the wart and the surrounding skin with tincture of iodine, injects a 2 per cent solution of procaine hydrochloride under the wart and then performs curettage in the direction of the skin clefts. The sharp curet lifts the whole wart from the underlying tissue without causing noticeable damage of the cutis. Since bleeding is undesirable, the author presses the artery that supplies the blood and then applies solution of potassium permanganate by means of a swab. The potassium permanganate solution not only is an effective hemostatic in cutaneous lesions but also has an antiseptic effect. During the first four days the dressing of the wound is changed three times and after that twice daily until complete healing has been obtained. At the change of dressing in the morning the entire area is wiped off with a swab that has been dipped into an oil benzene mixture (1:3). At the midday and evening change new gauze with ointment is applied, after the cavity has been cleansed with cotton that has been dipped into boric acid solution or into a 1:1,000 mercuric oxy cyanide solution. The second type of warts, the verrucae planae juveniles, which have a tendency to spontaneous cure, the author counteracts by applying once daily or every other day undiluted tincture of iodine (6.5 per cent). The third type of warts, the condylomata acuminata, he treats again like the verrucae vulgares, by means of curettage, potassium permanganate solution and so on.

## THE PREVENTION OF DEAFNESS

S J CROWE M D  
AND  
JOHN W BAYLOR, M D  
BALTIMORE

A laboratory was established at the Johns Hopkins University in 1924 for study of the causes and prevention of deafness. The plan of investigation was patterned after that used so successfully in general pathology, i. e. the correlation of impaired function as determined by clinical tests with the location and nature of the causal lesion. Systematic adherence to this plan for fourteen years has resulted in the accumulation of approximately 15,000 records of hearing tests, illustrating every type and degree of deafness, and has led us to conclusions that could not have been forecast. This communication deals with one phase of our investigation, which we believe is of the first importance in the recognition and prevention of the commonest type of deafness. A preliminary report on this subject was published in 1937.<sup>1</sup>

It was essential that the hearing test should be as accurate as possible and that each patient be followed and retested from time to time. Through the courtesy of the Bell Telephone Laboratories, we have used for these tests an audiometer with a range of tones from 32 to 16,384 double vibrations, which is not available in the commercial audiometers. As the number of records made with this audiometer increased, it became apparent that impaired hearing for high tones is extremely common in children as well as in adults. The classic teaching in otology has always been that "impaired hearing for high tones with good hearing for low tones" indicates an inner ear or nerve lesion, but the frequency with which we found this disorder in children led us to doubt the conclusion. Our doubts were increased after a clinical-pathologic study published in 1934<sup>2</sup> and by the observation that some children regain their hearing of high tones after removal of enlarged tonsils and adenoids. The fact that the hearing did not always improve after operation led us to examine the upper air passages, nasopharynx and eustachian tubes of these children in search of a cause. It is necessary to use a nasopharyngoscope to obtain a clear view of this region. With some children a satisfactory examination may require a general anesthetic, such as avertin with amylene hydrate, but the results justify the means.

During childhood the lymphoid tissue in the throat reacts to infection by increasing in size and spreading to areas of mucous membrane normally free from it, for brevity we designate this condition an overgrowth of lymphoid tissue. It often happens that, after removal of the tonsils and adenoids in children and in some adults, numerous nodules of lymphoid tissue appear on the lateral and posterior walls of the pharynx. This condition is called granular pharyngitis. Our nasopharyngoscopic examinations of children with high tone impairment that failed to clear up after operation showed a condition in the nasopharynx identical with granular pharyngitis and, in addition, overgrowth of lymphoid tissue in and around the pharyngeal orifice of the eustachian tubes.

This abnormal growth of lymphoid tissue partially obstructs the tubes, causes a hypersecretion of mucus, which further impairs function, and produces a chronic irritation in the tubes and middle ears. The earliest symptom of such a partial obstruction is impaired hearing for the tones between 10,000 and 16,000 double vibrations. Good hearing in the middle of the scale, from 250 to 3,000 double vibrations, is essential for understanding speech, and until hearing for the middle tones becomes impaired children with partial tubal obstruction may have no evident difficulty in hearing at school or at home or if they do it is ascribed to inattention. If untreated the deafness progresses by involving one octave after another toward the low end of the scale and becomes evident only when the tones in the speech range are affected. Thus the primary cause may be insidiously damaging the hearing apparatus for several years before it is recognized. The location makes it impossible to remove this hyperplastic lymphoid tissue surgically without further damaging the tubes. The work of Heineke<sup>3</sup> at the University of Leipzig, which in 1905 showed that lymphoid tissue is more susceptible to irradiation than the adjacent epithelium, muscle and bone, suggested to us the use of radium and roentgen rays in the treatment of this condition. Safe doses of roentgen rays or radium do not destroy or totally remove lymphoid tissue but do reduce its size and temporarily inhibit its growth. With the aid and advice of Dr Curtis F Burnam, we began about ten years ago to treat hypertrophied lymphoid tissue around the eustachian tubes with roentgen rays through portals near the angle of the jaw and with radium in an applicator small enough to pass along the floor of the nose. With a nasopharyngoscope in one side of the nose and the applicator in the other it is possible to place the applicator under visual control.

It was this combination of factors which led us to the conclusion that the most common type of middle ear

deafness in adults begins in childhood between the ages of 5 and 10 years. The primary cause is hyperplastic lymphoid tissue around and in the pharyngeal end of the eustachian tubes. When the tubal orifices are partially blocked from this cause, operative removal of the tonsils and adenoids must be supplemented by one or more radiation treatments. Complete obstruction of the eustachian tube causes acute middle ear symptoms

Chart 1—The acuity of hearing for the frequencies 10 121 13 004 and 16 384 double vibrations in an 11 year old child with normal hearing

and often abscess. The most common result of a long-continued partial obstruction during childhood is an insidious, slowly progressing deafness that begins with the highest tones. Pain, tinnitus, dizziness or other symptoms of ear trouble were absent in the majority of our patients. Recurring attacks of otitis media in children who have a tendency to lymphoid hyperplasia is the second most frequent symptom of a chronic, partial obstruction of the eustachian tube. A third symptom is long-continued discharge from the ear after paracentesis or after a simple or radical mastoid operation. There are other causes of chronic discharge but before one resorts to surgical operation the nasopharynx should be examined with a nasopharyngoscope and, if indicated, the function of the eustachian tube should be restored by suitable irradiation. We have found this supplementary treatment of great value. Occasionally it is necessary to pass a cotton-tipped Yankauer applicator through the eustachian tube, followed by gentle inflation, to remove plugs of thick mucus. The tube usually clears itself, however, after adequate irradiation, and unnecessary treatment causes irritation and a continued hypersecretion of mucus. Hyperplasia of lymphoid tissue in the upper air passages in response to every slight infection is most marked in children. After the age of puberty this type of reaction gradually disappears. If damage to the hearing apparatus and deafness later in life are to be prevented, one must do everything possible to improve the general condition and prevent recurring infections during childhood. This necessitates constant surveillance, particularly, frequent tests of hearing and repeated examinations of the tympanic membranes and nasopharynx.

When a condition around the orifice of the eustachian tubes is found that mechanically predisposes the child to ear infections or to deafness later in life, the first step is to take a careful history. Everything possible must be done to improve resistance and lessen the frequency of colds. For this reason the diet, clothing, digestion and number of hours of sleep should be inquired into. It is a mistake to put the child on an open porch or in a cold room at night, he should have an adequate amount of fresh air without undue expo-

sure. A general physical examination including a tuberculin test is made. The adenoids, tonsils and hypertrophied lymphoid tissue on the lateral walls of the pharynx and at the base of the tongue are thoroughly removed by surgical operation. Later another examination is made with the nasopharyngoscope, and if lymphoid nodules around the tubes are still present the area is treated with radium. The applicator is made of flexible steel wire threaded for the attachment of a piece of brass tubing 1.5 cm. in length, which is closed at one end. The radium is placed in the brass tube, the wall of which is 1 mm. thick and allows the passage of gamma rays but filters out most of the beta rays. We have used from 2 to 2.5 gram minutes on each side of the nasopharynx. It is better to give repeated small doses at intervals of a month or six weeks than to risk the irritation and edema that follow an overdose. The radium containing end of the applicator is held a few millimeters away from the surface of the lymphoid tissue being treated; the irritation or overtreatment of a localized area thus being avoided. It is never necessary or advisable to put the applicator directly into the lumen of the tube. If the hyperplastic lymphoid tissue in the pharynx is so diffuse that it cannot all be removed at operation or if it regenerates after every cold, we supplement the radium treatment with high voltage roentgen therapy. The total dose is 500 roentgens as calculated for the rays reaching the tissue being treated. This is given not at one exposure but in six treatments at intervals of four days. This may cause slight redness of the pharynx and discomfort on swallowing but causes no irritation of the skin.

We cannot emphasize too strongly that lymphoid nodules around the tubes may recur even after the most thorough operation and irradiation. The object of the operation is, by removing infected lymphoid tissue, to make the local condition in the nose and throat as favorable as possible for the normal function of the eustachian tubes, while the object of the irradiation is not to destroy or remove lymphoid tissue but to keep it in

Chart 2—The earliest stage of impaired hearing due to partial obstruction of the eustachian tubes with hyperplastic lymphoid tissue. Only the highest tones were affected. The frequency 16 384 double vibrations was not heard at the maximum intensity of the audiometer. More advanced stages of deafness from the same cause are shown in charts 3 and 4.

abeyance during the age period in which it grows most actively. By this method the hearing of children may be safeguarded and those already deaf from tubal obstruction may even be cured, as illustrated by the following case reports.

CASE 1—E. F., a boy, brought to the Johns Hopkins Hospital in 1932, when 10 years of age with marked impairment of hearing, during the first four years of life had had frequent colds that began with a sore throat and nasal congestion and usually terminated in a prolonged attack of bronchitis. In

several of these attacks his ears became infected and his tympanic membranes either ruptured spontaneously or were opened by paracentesis. For the relief of these symptoms his tonsils and adenoids were removed when he was 4 years old. After this operation the acute attacks were less frequent and he had no further earache or discharge, but he continued to have frequent colds and his hearing became progressively worse.

Physical examination showed nothing abnormal except in the ears and upper air passages. The tympanic membranes were intact but extremely retracted, scarred and opaque. The accessory nasal sinuses were not infected, but the adenoids had reappeared and were so large that they completely covered the orifices of both eustachian tubes. The lymphoid tissue on the lateral and posterior walls of the pharynx and at the base of the tongue was enlarged and infected. This hyperplastic lymphoid tissue was removed as thoroughly as possible with the idea of decreasing the area to be irradiated and thereby decreasing the dose of roentgen rays or radium necessary to restore the normal function of the eustachian tubes. For eight months after this operation the child had no colds, his hearing improved and the hyperplastic lymphoid tissue around his tubes regressed somewhat. The hyperplasia recurred, however, after the first cold, and his hearing gradually became worse. His hearing test at this time (March 1933) is shown in chart 3.

The nodules of lymphoid tissue, after two operations for their removal were so diffusely scattered over the pharynx and nasopharynx that the patient was referred to Dr Charles A. Waters in March 1933 for a series of roentgen treatments. It would probably have been wiser to do this in the first place. Over a period of a month he received 1,132 roentgens over the external auditory canal on each side, 468 roentgens over the tonsillar region on each side and 1,404 roentgens anteriorly over the base of the tongue and pharynx. For several weeks after these treatments his hearing was worse, owing no doubt to edema of the mucous membranes in the middle ear and eustachian tubes. After this it slowly improved. In November 1933 he had a second series of roentgen treatments and received 1,344 roentgens directed toward the nasopharynx on each side. His hearing rapidly improved and it remained good until March 1934, when hearing for the higher tones again became impaired in the left ear (chart 3). This was due to pneumonia with a mild secondary infection of the mucous membrane around the left eustachian tube. With no local treatment of any kind this condition cleared up and the hearing again improved, as shown in chart 3 (April 1934).

During the next twenty-one months the patient had no severe colds and no trouble in hearing. In February 1936 after a 'slight head cold' with no sore throat, cough or fever, he again became quite deaf (chart 3). The lymphoid tissue in the nasopharynx was again hypertrophied and completely covered the orifice of the tubes. Radium was used and only the pharyngeal orifice of the tubes was treated. A 276 millicurie applicator, shielded with brass, was passed along the floor of the nose and under direct vision with a nasopharyngoscope in the opposite side, each eustachian orifice was irradiated for eight minutes a dose equivalent to 22 gram minutes of radium.

After this treatment, in February 1936 the hearing improved reaching normal by August 1936. The patient was next seen in October 1938, when in response to our request he returned for another examination. He was then 17 years of age, weighed 160 pounds (73 Kg.), rarely had a cold and had no noticeable impairment of hearing (chart 3). His tympanic membranes were scarred, opaque and retracted, especially Shrapnell's membrane but his hearing was good and he had apparently passed the period of active lymphoid hyperplasia. It is worthy of note that at no time did he have a eustachian tube dilation or inflation. His only treatment was irradiation for the purpose of keeping the tubes open and clear of mucus.

CASE 2—The first ear trouble of R. B. a boy occurred in 1930 at the age of 3 following removal of his tonsils and adenoids. Both tympanic membranes ruptured and the discharge continued for several weeks. Three years later his tonsils and adenoids were again removed because of deafness, recurring colds, enlarged cervical glands, a continuous fever and extreme nervousness suggesting chorea. His hearing improved and for a year he was well but after measles in

December 1933 his hearing again became impaired, although there was no pain or discharge. He was brought to the Johns Hopkins Hospital in September 1934 because his hearing was growing progressively worse. He had a hearing loss of approximately 25 per cent which was due to diffuse nodular hyperplasia of lymphoid tissue in the nasopharynx, on the lateral and posterior pharyngeal walls and at the base of the tongue. The tissue was removed with the patient under general anesthesia. This was the third time lymphoid tissue had been removed during four years. We now know that the results would have been better if, instead of this operation, the patient had been given a series of high voltage roentgen treatments. The orifices of both eustachian tubes were overgrown with

Chart 3 (case 1)—This series of audiograms shows clearly the effect on hearing of irradiation of hyperplastic lymphoid tissue in and around the orifices of the eustachian tubes. It also shows the necessity for frequent hearing and nasopharyngeal examinations as well as repeated radiation treatments. Note the similarity between the April 1934 audiogram and chart 2.

lymphoid tissue but at this time we were uncertain about the effect of nasopharyngeal irradiation on the pituitary gland and nothing more was done for a year and a half.

At a second examination, in April 1936 the general physical condition was found to be much improved and the lymphoid hyperplasia in the pharynx and at the base of the tongue had not recurred, but the local condition in the nasopharynx was unchanged. The tympanic membranes were retracted, tuning fork tests indicated a middle ear lesion with good bone conduction and the audiometer test showed impaired hearing in both ears (chart 4 April 1936). The patient was given his first radium treatment, a 2 gram minute application over each eustachian orifice. Six months later the pharyngeal orifices of the tubes appeared more normal than at any previous examination and his hearing was so much improved that for the first time in two years he heard tuning forks better by air than by bone conduction. The improvement was only temporary. After a cold the tubes again became partially blocked with lymphoid

tissue, and the test in July 1937 showed that his hearing was more impaired on the right side (chart 4). Three weeks after the second radium treatment, 2 gram minute application over each eustachian tube, acute otitis media developed in the right ear and his hearing in both ears became worse than before the irradiation. This was probably due to the irritating beta

Chart 4 (case 2)—It was unusually difficult in this case to keep the eustachian tubes clear of lymphoid tissue. Frequent radium treatments over a period of two years were necessary to restore the hearing. We shall continue to examine the child every six months and give further radium treatments if necessary.

rays. The applicator either was held too close to the orifice of the tubes or was improperly screened. Since then the patient's hearing has gradually improved (chart 4, October 1937-1938), although he has had no further treatment of any kind.

The patient is now 11 years of age, is in excellent physical condition and rarely has a cold, and his upper air passages, including the pharyngeal orifices of the eustachian tubes, are normal in every way. His hearing is so nearly normal on both sides that he has no difficulty in school work.

CASE 3—E O., a girl, probably began to have impairment of hearing in infancy, although it was not noticed until she was 8 years of age. She had otitis media at the age of 2, and at this time her tonsils and adenoids were thoroughly removed. The ears stopped discharging after this operation, but she continued to have difficulty in breathing through her nose. When first seen in the outpatient department of the Johns Hopkins Hospital, in April 1935, she was 7 years old but the true nature and implications of her trouble were not recognized. Her nasal mucous membranes were congested, her nose was filled with discharge, and nodules of hypertrophied and infected lymphoid tissue were seen on the lateral and posterior walls of her pharynx, but on palpation no enlarged adenoids were found. Both tympanic membranes were retracted but otherwise looked normal. It was thought that her trouble was due to a sinus infection. She was difficult to examine and treat and did not return until a year later. She came then because her teacher had noticed that she was partially deaf.

At the second examination her hearing was found to be markedly impaired (chart 5, April 1936). The low tones were

heard better than the high tones. None of the tones above 2,896 double vibrations on the right or 5,793 double vibrations on the left were heard at the maximum intensity of the audiometer. The 512 double vibration fork was not heard by bone conduction. She was then examined under general anesthesia with a nasopharyngoscope. The adenoids in the midline of the nasopharynx were not enlarged, but the orifices of the eustachian tubes were completely covered with nodules of lymphoid tissue, similar to those in the pharynx.

The lymphoid nodules on the lateral and posterior walls of the pharynx were removed and at a later date the region around the pharyngeal orifice of the tubes was treated with radium. The hearing improved, the nasal congestion and discharge disappeared and the audiometer test made about fourteen months later showed approximately normal hearing for both ears (chart 5, June 1937).

This case alone refutes the universally accepted idea that such an extreme degree of deafness, with the high tones more affected than the low tones and a total loss of hearing by bone conduction for the 512 double vibration fork, is always due to an inner ear or nerve lesion. The child had no treatment of any kind aside from the operation and the irradiation of the pharyngeal end of the tubes, but hearing for 4,096 double vibrations and

Chart 5 (case 3)—The most striking improvement in hearing resulted from irradiation of eustachian tubes obstructed by lymphoid tissue. The hearing test of April 18 1936 was typical of an inner ear or nerve deafness. The higher tones were not heard by air and the 512 double vibration fork was not heard by bone conduction. In June 1937 the hearing was good for all high tones by air and normal by bone conduction.

all higher tones returned almost to the normal level. When the entire series of cases is considered, showing the hearing in all stages of impairment for high tones and for bone conduction and its return to the normal level, it is certain that the interpretation of hearing tests must be radically revised. An apparently hopeless deafness can be cured if it is recognized and treated early but

is incurable if allowed to progress until secondary changes in the middle ear embed the ossicles in scar tissue and adhesions

CASE 4—R S, a boy aged 11 years, was brought to the outpatient department in October 1935 because of progressive impairment of hearing for three years. He had never had

Chart 6 (case 4)—The impaired hearing in October 1935 was due to partial obstruction of the eustachian tubes with lymphoid tissue. The audiograms for the right and left ears differ markedly. The tubal obstruction and middle ear changes are more advanced on the right. The audiogram for the left ear when compared with chart 2 and with the audiograms of March 30 1934 in chart 3 and April 19 1936 in chart 5 shows that deafness begins with the high tones and progresses by involving one octave after another toward the low end of the scale

an ear infection but was a mouth breather and had had occasional attacks of tonsillitis. There was no history of deafness in the family. The general physical examination showed nothing abnormal except in the ears and upper air passages. The tonsils were enlarged and the orifices of both eustachian tubes completely covered by an overgrowth of lymphoid tissue. The tympanic membranes were much retracted but otherwise normal. No evidence of sinus infection was seen.

The first audiometer test in October 1935 showed an impairment greater on the right for low tones but very severe on both sides for all high tones above 2,048 double vibrations (chart 6). It is noteworthy that the hearing was better by air than by bone and bone conduction for the 512 double vibration fork was greatly shortened. Ten days later the tonsils and adenoids were removed. The patient was not seen again until April 1936 when his mother brought him back because his hearing had failed to improve. No audiometer test was made at this time but on examination with the nasopharyngoscope it was seen that the eustachian orifices were still occluded with lymphoid tissue. He has had only one radium treatment (April 1936) with a nasal applicator screened with brass for 15 gram minutes on each side. The second audiometer test in August 1936 showed normal hearing in both ears (chart 6). The nasopharynx and tubal orifices were normal. When the patient was seen in October 1938 his hearing was good both subjectively and objectively (chart 6). It is noteworthy that

as hearing improves the hearing for the highest tones is the last to reach the normal line. We have repeatedly observed that with children the highest tones are the first to be affected during the earliest stage of partial obstruction of the eustachian tubes by an overgrowth of lymphoid tissue.

The first diagnosis was a combined middle and inner ear deafness, but the absence of improvement in the six months following the removal of the tonsils and adenoids and the very striking improvement following irradiation shows that this diagnosis was incorrect. One radium treatment cleared away the lymphoid tissue around the tubal orifices. With the restoration of function of the tubes the hearing for conversation returned to normal, and it has remained so for more than two years. Hearing for some of the high tones has improved as much as 60 decibels. If a partial obstruction of the tubes is not corrected during childhood it is certain that later in life permanent deafness will result from irreparable changes in the middle ears.

This boy is now 14 years old and has good hearing in both ears, and now that he has passed the age of excessive lymphoid hyperplasia there is every reason to think that his hearing will remain good.

CASE 5—J H, a boy, had increasing deafness, which made it impossible for him to keep up with his class at school and frequent colds and mouth breathing, and the school physician advised his parents to have his tonsils and adenoids removed. This was done, but very inadequately, in the spring of 1937. During the next year the symptoms all became worse. His hearing was so poor that the school authorities transferred him to a special class for handicapped children where he was taught lip reading. We first saw him in June 1938 and found that his tonsils had been partially removed, that the pharyngeal orifices of both eustachian tubes were completely obscured with

Chart 7 (case 5)—The spectacular improvement resulted from adenoidectomy, followed by radium treatment of the remaining hyperplastic lymphoid tissue around the orifices of the eustachian tubes. A year before our first examination the patient had been transferred to a special school for deaf children and taught lip reading. Now he is back with normal children and doing well in his studies.

nodules of lymphoid tissue and that the tympanic membranes were intact but markedly retracted. He was almost totally deaf (chart 7 June 1938). He failed to hear the high tones by air conduction at the maximum intensity of the audiometer or a 512 double vibration steel fork at maximum intensity by bone conduction. The observations were typical of severe inner ear deafness.

The remaining tonsil and adenoid tissue was removed, together with the hypertrophied lymphoid nodules on the posterior and lateral walls of the pharynx. Later the lymphoid tissue in and around the eustachian tubes was treated with radium. An applicator containing 147 millicuries was passed along the floor of the nose and held over the eustachian orifices for fifteen minutes on each side, a dose equivalent to 22 gram minutes of radium. The ears were not inflated at any time. Within a week the hearing began to improve and when the second audiometer examination was made eighteen days after the first test his hearing was found to be practically normal on both sides for air and bone conduction. At our request the patient's mother brought him back for an examination in November 1938, just five months after the operation and irradiation. During this short period he had been transformed from a dull, listless, almost totally deaf child who had been in a lip-reading class for nearly a year to a bright, alert, healthy looking boy with good hearing in both ears (chart 7 November 1938). At the beginning of the school year in September, he was put back into a class of children with normal hearing and is doing good work. At the first examination he did not hear the higher tones even at the maximum intensity of the audiometer or the monochord and heard nothing by bone conduction. The improvement shown by the second examination has been maintained and extended particularly for bone-conducted sounds. We can offer no explanation of the latter phenomenon. The only objective finding to explain it is the disappearance of the lymphoid tissue in and around the pharyngeal orifice of the eustachian tubes. The only adults in whom we have seen a comparable improvement in hearing for air and bone conduction had Meniere's disease.<sup>4</sup> In these patients the eustachian tubes and middle ears were normal and the improvement was spontaneous and not the result of any form of treatment.

This case emphasizes the necessity for a revision of diagnostic methods for differentiating middle and inner ear lesions and proves that in children an apparently hopeless deafness may be cured.

#### SUMMARY

A long-continued partial obstruction of the eustachian tubes in children causes retraction of the tympanic membranes, impaired hearing for high tones with relatively good hearing for low tones, and sometimes a total loss of hearing by bone conduction. This revolutionary statement is based on detailed observation of sixty children, in some cases for ten years. In all of them the pharyngeal orifices of the eustachian tubes were partially occluded with nodules of lymphoid tissue. This condition in the nasopharynx is identical with granular pharyngitis but is more difficult to see. The location of the hyperplastic lymphoid tissue interferes with the normal function of the tubes. The most satisfactory method of treatment is irradiation with radium or roentgen rays. After the hyperplastic lymphoid tissue has been reduced and the tubal orifices look normal when viewed with the nasopharyngoscope, the hearing for high tones and for bone-conducted sounds often returns to the normal level, and it remains there so long as the eustachian tubes are clear. After a cold the original condition may recur, with consequent loss of hearing. This proves that impairment or even total loss of hearing for high tones and for bone conducted sounds does not necessarily imply an inner ear or nerve lesion.

Complete obstruction of the eustachian tube causes acute middle ear symptoms and often abscess. Partial obstruction in children causes a progressive loss of hearing, beginning with the high tones and gradually involving the low tones. If the causal condition is recognized and properly treated before the age of 15, hearing usually returns to somewhere near the normal level.

After this age the results are far less satisfactory, because hyperplastic lymphoid tissue and partial tubal obstruction usually date from early childhood. After the age of 15 the secondary changes in the middle ear may be so advanced that they can be repaired by no treatment whatever.

Irradiation does not permanently remove hyperplastic lymphoid tissue, but relatively small doses, which in no way injure the pituitary gland, nasopharyngeal mucosa or inner ear, keep it in abeyance during the age period in which it grows most actively.

We conclude from our studies that the most common type of middle ear deafness in adults begins during childhood. It often progresses so gradually and insidiously that it may not become evident, i. e., the frequency range of speech is not involved, until it is too late to correct the primary trouble and restore the hearing. We feel that if school children in the primary grades were examined with a nasopharyngoscope at least once a year and those with hyperplastic lymphoid tissue in and around the orifice of the eustachian tubes were treated with radiation as often as necessary to insure normal functioning of tubes, the number of deaf adults in the next generation could be reduced by 50 per cent.

## HORSE SERUM NEURITIS

WITH REPORT OF FIVE CASES

A. E. BENNETT, M.D.

OMAHA

While the potential dangers of immediate and delayed reactions following parenteral administration of horse serum are well recognized by the medical profession, the possibility that serum sickness may result in serious complications is not as well known. One of the most serious sequels following prophylactic and therapeutic injection is horse serum neuritis.

Serum sickness, a delayed type of reaction, occurs from six to fourteen days after the injection of horse serum. It is in no way dependent on atopic, hereditary sensitiveness or anaphylaxis (artificial sensitization by previous injections that at times causes immediate, life endangering reactions). Serum sickness probably would occur in all cases if enough serum were given. Local itching, swelling, generalized urticaria, fever, enlargement of lymph glands, polyarthritides, general malaise, leukopenia, albuminuria, fall of blood pressure and decreased coagulability of the blood make up the complete clinical picture.

The severity of the reaction varies greatly. The cause is in no way understood. Size of the dose, age and degree of purification and concentration, type of bacteria, peculiarities of serum from certain horses and route of administration are factors, but the exact cause of the sickness is not known.

In a small minority of cases, neurologic complications occur at the onset or height of serum disease. While cerebral, meningeal and spinal lesions occur, the commonest involvement is in peripheral nerves. Also in a large percentage of cases the nerves from the cephalic part of the brachial plexus (fifth and sixth cervical roots) are involved.

From the Department of Neurology, University of Nebraska College of Medicine.  
Read before the Section on Nervous and Mental Diseases at the Eighty-Ninth Annual Session of the American Medical Association, San Francisco, June 17, 1938.

## SYMPTOMS OF SERUM NEURITIS

Within a few hours after the onset of serum sickness and generalized urticaria, severe neuritic pains develop. The pains usually involve the neck, shoulders, arms and legs and are so severe that analgesic and opiate medication gives little relief. Flaccid paralysis occurs within a few hours to a day or two and it is followed by gradual atrophy of muscles. Muscle tenderness, hyperesthesia and dull pains persist for several weeks. The neurologic signs, depending on the neural segments involved, consist of motor paralysis, atrophy, at times fibrillations, sensory loss and reduced or absent reflexes.

## PATHOGENESIS OF SERUM NEURITIS

Just as the exact cause of serum disease is not known, the exact cause of the occurrence and localization of serum neuritis is not known. Early authors, for example Richardson,<sup>1</sup> offered the explanation of a direct toxic action of serum on nerves. Others for example Bourguignon<sup>2</sup> and Pessin,<sup>3</sup> have favored the theory that protein toxins affect muscles innervated by nerves of low or medium chronaxia. Most writers—Kennedy,<sup>4</sup> Young,<sup>5</sup> Allen,<sup>6</sup> Kraus and Chaney,<sup>7</sup> Wilson and Hadden<sup>8</sup>—offer the more plausible theory of perineural urticaria and edema producing a compressive or ischemic paralysis of nerve trunks or peripheral nerves.

The common site of involvement of the upper brachial nerves (fifth and sixth cervical nerves) producing the characteristic Erb-Duchenne scapulohumeral palsy is not explained. The largest percentage of reported cases are of involvement of the suprascapular nerve combined at times with involvement of the axillary nerve or long thoracic nerve, all from the fifth, sixth and seventh cervical nerves. To explain this localization there must be some localized anatomic condition similar to the compressive neuritis of Bell's facial palsy or the compression of the scalenus anticus muscle associated with cervical rib neuritis. Associated with serum sickness are intense vasodilatation and edema of skin, muscles, bursae and joint tissues. Perineural urticarial compression of these nerve trunks for a few hours could produce the palsy.

It seems possible that this edematous process may occur in the intervertebral foramina, bony grooves or perineural sheaths of the roots or nerves, interfering with the blood supply and causing impairment of nutrition or anoxemia with temporary nerve cell and fiber death. The experiments of Garcin and Bertrand<sup>9</sup> and Dechaume and Croizat<sup>10</sup> with animals showed, after repeated anaphylactic shock phenomena of vasodilatation, perivascular infiltration and at times minute

hemorrhages with cellular destruction and marked meningeal reactions. Increased lymphocytosis has been observed frequently in the spinal fluid during the serum sickness stage. Possibly then a combination of a vascular disorder and edematous compression accounts for the neuropathologic picture of complete peripheral nerve palsy and muscular atrophy. The anterior horn motor neurons must be unaffected, because complete regeneration usually occurs.

Another etiologic factor is age. Almost all reported cases have been in adults, the average age being 26. Men are more frequently affected than women. In over half the reported cases the complication has followed the prophylactic use of tetanus antitoxin, but practically all types of horse serum antitoxin have produced it.

## REVIEW OF LITERATURE

Most of the reported cases are from France, about seventy to 1938. Twenty-nine authentic cases have been found in the English literature, ten have been reported from Germany and a few isolated ones from Denmark,<sup>11</sup> Italy, Poland, Rumania, Japan and Switzerland. Approximately 115 cases have been reported. It is difficult to be exact, because many complications from vaccine therapy and other allergic manifestations with neurologic complications are included in some reports. These are not true post-serum sickness neuritis.

The first accurate case reports were made by Grudiere and Gangolphe<sup>12</sup> in 1908, Thaon<sup>13</sup> in 1912 and Vincent and Richet<sup>14</sup> in 1911 in France. The first American case was reported by Richardson<sup>1</sup> in 1917, Dyke<sup>15</sup> of England in 1918 described a typical case, in which the neuritis followed the prophylactic injection of tetanus antitoxin for war injuries. Lhermitte<sup>16</sup> reporting in 1919, stimulated renewed interest in France. The many succeeding authentic case reports have been summarized best by Kennedy<sup>4</sup> in the United States, Allen<sup>6</sup> in England in 1931, Young<sup>5</sup> in the United States in 1932, Doyle<sup>17</sup> in the United States in 1933, Vogel<sup>18</sup> in Germany in 1935, Roger and Poursines<sup>19</sup> in 1932, Mignot<sup>20</sup> in 1936, Kraus and Chaney<sup>7</sup> in 1937, Schipkowensky<sup>21</sup> in 1937 and Chavany and Askenazy<sup>22</sup> in 1936.

## TREATMENT

*Prophylaxis of Serum Disease*—There is no known method of desensitization to prevent serum sickness nor any way of detecting susceptible persons, as with atopic or anaphylactic types. The only sure prophylaxis would be the substitution of other animal serums.

for horse serum.<sup>23</sup> The development of tetanus immunization by alum-precipitated toxoid would eliminate the larger percentage of complications.<sup>24</sup>

*Prophylaxis of Post-Serum Sickness Neuritis*—It appears to me to be much more feasible to prevent the serious complication of neuritis or at least the extreme atrophic types by early recognition. The development of neuritis can be detected early by the characteristic neuritic pains following generalized urticaria. Shoulder, joint or muscle pains sufficiently severe to require opiates are suggestive of radical involvement. Measures directed toward reducing vasodilatation and urticarial swelling should reduce the perineural edema and lessen residual neural damage. Intravenous injections of hypertonic sucrose or dextrose solution and artificial hyperpyrexia (103 to 104 F for two hours) or blanket sweat packs with pilocarpine would dehydrate muscle, joint and neural structures, relieve pain and tend to restore normal nerve function.<sup>25</sup> Repeated injections of epinephrine, which are so effectual in relieving urticarial swelling, probably lessen nerve damage.

*Treatment of Neuritis*—After the serum sickness stage the treatment is largely symptomatic. An abduction splint and complete rest of the arm are indicated during the acute stage. General nutritive and vitamin therapy may be of value. Local and general heat therapy relieves neuritic pain, muscular tenderness and hyperesthesia, which may persist for some weeks. After the hyperesthetic stage, physical therapy such as massage and electrical stimulation similar to the treatment for poliomyelitis, are indicated.

#### PROGNOSIS

Patients having profound atrophy within six weeks after serum disease are slowest to recover. However, even those with advanced atrophy and absence of electrical reactions tend to recover. About 20 per cent are left with residual weakness and atrophy, especially of the deltoid muscles. The large majority recover in about six months. Recovery occurs as late as eighteen months after injury.

#### MEDICOLEGAL ASPECTS

The medicolegal aspects are of extreme economic importance, as in a large percentage of cases the neuritis develops after industrial wounds and prophylactic administration of tetanus antitoxin. It is directly the result of the treatment administered for the accidental wound and is compensable. Insurance companies have to accept this fact and recognize the risk, since physicians must give prophylactic injections of tetanus antitoxin. However, greater care can be exercised by the physician in giving prophylactic serum only for dirty or penetrating wounds. Patients who have previously had neuritis are particularly susceptible to reactivation with serum sickness.<sup>18</sup> An explanation of the symptoms of serum sickness should be given to the patient with instructions to call the physician if severe neuritic pains develop in order that he may administer early curative treatment.

In an attempt to obtain facts concerning the compensation experience of leading insurance companies, a questionnaire was sent to eighteen companies or commissions. Replies were received from eleven companies. Six said that they had had no experience relative to complications following serum sickness. Two replied that they had had claims for this type of disability, but no facts were given. One stated they had had one serious claim, but the facts were unobtainable. The Travelers Insurance Company, through Dr James C Graves, supplied data concerning two typical cases of palsy of the upper brachial nerves following tetanus prophylaxis. One patient recovered in five months, with compensation of over \$500. The other had not recovered since July 1937, he was still being carried on the basis of a 50 per cent disability of the arm, and the total amount of the claim was not stated. Another company reported a case in which brachial neuritis on the right side, with aphasia, occurred at the height of serum sickness following prophylactic injection of tetanus antitoxin, the disability lasted six months, with an approximate compensation cost of \$2,000.

Finally, physicians should avoid indiscriminate injections of horse serum antitoxins which are nonspecific in their action or of which the therapeutic value is questionable, for example antistreptococcus, antistaphylococcus or antigonococcus serums. Other therapy less dangerous had better be substituted.

Only by a more general knowledge of the facts regarding neurologic complications of horse serum inoculation can the physician remove these unfortunate sequelae.

#### REPORT OF CASES

CASE 1—J M, a youth aged 16, July 4, 1933, received a burn of the left hand from a firecracker. The family physician treated it and injected 1,500 units of tetanus antitoxin into the left deltoid region. Seven days later generalized urticaria, malaise, fever and joint pains developed. Very severe pains, persisting for about six weeks, occurred in the right elbow, shoulder and arm. Two days after the onset the patient was unable to lift the right arm. He was referred for neurologic examination about August 4. At that time he complained of loss of weight and numbness of the right shoulder region. He had received an injection of diphtheria toxin antitoxin at the age of 13. There was no history of an allergic tendency.

Examination disclosed marked atrophy with complete loss of motor power of the deltoid, supraspinatus and infraspinatus muscles of the right shoulder. There was also moderate weakness of the right biceps. Loss of pain and touch sensation was present over the deltoid area. The biceps reflex was diminished. Extreme muscular tenderness was present over the atrophic muscles and brachial plexus. No response was elicited by faradic stimulation of the atrophied muscles.

Local diathermy treatments to the right arm and shoulder were given, together with analgesic medication. The patient's arm was kept at complete rest. After about three months the motor power gradually returned and the muscle atrophy disappeared, and by the end of about six months the muscles appeared normal. A complete neurologic examination four years later, Dec 29, 1937, revealed no evidence of residual weakness, atrophy or reflex disturbance. Recovery from a severe grade of serum neuritis of the upper part of the brachial plexus was complete.

CASE 2—W J, a man aged 56, Sept 27, 1935, received a severe laceration and compound fracture of the right ankle and leg from a mowing machine. Fifteen hundred units of tetanus antitoxin was injected into the arm muscles. Because of the severity of the injuries, the patient was referred to a surgeon in a city hospital. Cultures of material from the wounds revealed *Bacillus welchii*, and 60 cc of gas bacillus antitoxin was given. The patient was critically ill for two

weeks, with a temperature as high as 106 F. About October 15 a serum reaction, generalized joint pains and urticaria, with a temperature of 100.5 F, developed. At the same time severe pains through the right shoulder, arm and hand, with numbness along the ulnar distribution, and tremor of the hand occurred. Muscular wasting of the shoulder muscles and small muscles of the right hand gradually developed.

Physical examination, with otherwise essentially negative results, revealed focal infection of the teeth and tonsils gen-

eralized undernutrition and an open, draining wound in the right leg. Neurologic examination showed nothing abnormal except in the right upper extremity.

Motor power was markedly reduced in all the shoulder muscles, especially the supraspinatus, infraspinatus and deltoid. Motor weakness was also present in the biceps and the muscles of the forearm, with one-half inch to an inch of atrophy. The hand grip was reduced and abduction and adduction of the fingers were lost. Marked atrophy of the shoulder girdle and intrinsic hand muscles was present. Hyperesthesia in the shoulder and arm muscles was present, otherwise the

Fig 1—Marked atrophy of the right supraspinatus, infraspinatus and deltoid muscles.

sensory examination gave negative results. The biceps and triceps reflexes on the right were still present but were markedly diminished.

The patient recovered from the fracture and wound of the ankle. Gradually the neuritic pains subsided after about three months, motor power gradually returned and the muscular atrophy disappeared. Reexamination six months later revealed almost complete functional recovery from the fairly complete serum neuritis of the brachial plexus.

CASE 3—R. G., a man aged 26. March 2, 1937, punctured the left hand with pruning shears. Fifteen hundred units of tetanus antitoxin was injected into the left upper arm muscles. The wound healed without infection. Eight days later severe pains developed in the right shoulder region. The patient was confined in bed for two days and complained of generalized aching throughout the body, especially the joints, and had a slight cutaneous eruption. The severe shoulder pains continued, the patient gradually losing the ability to raise the right arm from the side. In about six weeks he noted wasting of the shoulder muscles. As the pains lessened he attempted to work but was unable to use the right arm. He had also noted an area of numbness over the right upper arm. About 15 pounds (7 Kg) loss of weight occurred and at times the left shoulder muscles were painful. The patient received no special treatment for five months and a diagnosis was not made.

The past history was unimportant. No atopic tendency was present and the patient had never received an injection of serum.

Physical examination August 13 gave essentially negative results. Neurologic examination, except for the upper extremities, revealed nothing abnormal. On inspection gross atrophy of the right side of the shoulder girdle was apparent (fig 1). The deltoid, supraspinatus, infraspinatus and teres muscles were almost completely absent. The patient was totally unable to elevate the right arm, backward extension was very weak. The remainder of the arm muscles were in normal tone. The sensory examination revealed nothing abnormal except extreme

tenderness of muscles and nerve trunks. A few fibrillary twitchings and myxedema were seen. The reflexes were all present. The left shoulder muscles were painful to pressure and muscular irritability was present on percussion, otherwise the left upper extremity was normal. Faradic stimulation elicited no muscular contraction from the atrophic muscles.

The patient was hospitalized August 16 and six artificial fever treatments three hours at a temperature of 103 to 104 F were given at three day intervals. Prompt and complete relief of pain occurred. A high vitamin diet, with additions of vitamin B<sub>1</sub> and injections of liver extract, was given. After the soreness of the muscles disappeared light massage was given to the atrophic muscles, but otherwise immobilization of the shoulder was carried out. Examinations were carried out every thirty days. The right triceps reflex was gradually reduced until it was absent. The atrophy of the deltoid muscles progressed. The patient gained 10 pounds (4.5 Kg) in weight. Faradic responses were not elicited in the atrophic muscles. Jan 1, 1938, compensation on the basis of 50 per cent permanent loss of function in the right arm was paid the patient. Observation one year after the serum sickness revealed no improvement in the condition.

This patient's neuritic involvement was more severe than that of the other four patients, and he was the only one who failed to obtain a functional recovery. One can only speculate as to whether earlier treatment might have lessened the total disability. The fact that he received compensation for one year and a settlement on the basis of 50 per cent permanent disability of the arm illustrates the economic problem of insurance compensation in industrial cases.

CASE 4—G. C., a man aged 29, Aug 4, 1937, received a nail puncture wound of the foot. Fifteen hundred units of tetanus antitoxin was injected into the left upper arm muscles. One week later mild generalized urticaria occurred with generalized aching. A few hours later very severe pains began in both

shoulders. A physician was called in the night, but in spite of several hypodermic injections of narcotics and strong sedatives he was unable to obtain relief of pain. Within twelve hours after the onset of pain the patient was unable to lift the left arm. The pains gradually lessened in severity but were replaced by a burning sensation throughout the left shoulder muscles. An area of numbness appeared over the left deltoid muscle. Gradually the patient noticed wasting of the left shoulder muscles. A 5 pound (2 Kg) loss of weight occurred. Otherwise the general health remained good. The patient had always had

excellent health, the only previous administration of serum had been for immunization against diphtheria.

Physical examination August 26 gave essentially negative results throughout. Neurologic examination revealed nothing abnormal except in the left upper extremity. On inspection the left shoulder was seen to be grossly atrophic, the left supraspinatus, infraspinatus and deltoid muscles were three-fourths inch smaller than and the left biceps one-half inch smaller than the right (fig 2). The patient was totally unable

Fig 2—Moderate atrophy of the left supraspinatus, infraspinatus and deltoid muscles.

to elevate the arm or raise the hand to the head. Marked weakness of external rotation and of forward flexion likewise were present. Both biceps and triceps reflexes were present. Marked muscular irritability was present, and the patient was very tender over the shoulder muscles and in the region of the brachial plexus. An area of total anesthesia and analgesia was present corresponding to the left circumflex nerve distribution over the deltoid. The atrophic muscles did not contract on faradic stimulation.

The patient was hospitalized for active treatment. Six artificial fever treatments of three hours, at a temperature of 103 to 104 F., were given at intervals of three days together with vitamin therapy. The neuritic pains, tenderness and anesthesia were entirely gone in three weeks. The patient gained 10 pounds (4.5 Kg.) in weight. The muscular atrophy progressed slightly. Active daily massage was carried on. Four months after the serum sickness the patient showed the first signs of regaining motor power. A definite response to electrical stimulation occurred and he was able to contract the deltoid muscle sufficiently to hold the arm horizontally for a moment. One month later he was able to carry out all movements of the shoulder but the muscles fatigued readily. The atrophy was disappearing. Two months later, about seven months after the injury, slight residual atrophy remained with weakness of abduction, extension and flexion of the upper arm. The patient resumed light manual labor.

The early treatment instituted relieved the acute neuritic manifestations, especially the pain, and probably prevented progression to the extreme atrophic stage of case 3. This may have been an important factor in the recovery. The patient received compensation for seven months, which illustrates the importance of the problem these complications present for insurance companies.<sup>26</sup>

CASE 5—A. L. A., a man aged 26, had always had robust health. At the age of 15 he received antitoxin for diphtheria immunization. Aside from occasional attacks of hives from bee stings and ingestion of fruit, he had no history of allergy.

At the age of 19, Aug. 5, 1931, he received a puncture wound of the foot. Fifteen hundred units of tetanus antitoxin was injected in the left upper arm. Seven days later severe urticaria developed, requiring three hypodermics of epinephrine in five hours for relief. Twelve hours after the onset of urticaria severe pains developed in all four extremities, especially severe in both shoulders and the left arm. After twenty-four hours as the severe pains were subsiding, the patient noted complete inability to extend the fingers and thumb of the left hand. He was also unable to extend the left elbow because of pain and swelling of the joint. The condition lasted one week. The loss of extension of the fingers continued, but extension, pronation and supination of the wrist remained. Numbness over the dorsum of the hand was also present. The only way the fingers could be extended was by complete flexing of the wrist. No muscular atrophy appeared.

The patient received electrical massage for several months. Seven months after the onset of paralysis the extensor power of the fingers returned.

This patient suffered partial radial neuritis after serum sickness and made a complete recovery in seven months.

#### SUMMARY

Horse serum neuritis, a severe sequel of serum sickness, develops at the height of the serum disease, usually one week after the injection of serum. Any type of horse serum can produce it, but in the majority of cases it follows injection of tetanus antitoxin. The neuritic type of pain is classic, and an early diagnosis of the complication can be made.

The cause of serum sickness and its neuritic complications is unknown. Perineural edema producing compressive neuritis seems the logical cause. In a large

majority of cases a peculiar anatomic localization occurs, involving the cephalic part of the brachial plexus (fifth and sixth cervical nerves). About 115 authentic cases have been recorded in the world literature during the past thirty years.

The ideal treatment would be prophylaxis of serum sickness by substitution of other serums for horse serum.<sup>23</sup> Early diagnosis of the neuritic complication with adequate treatment should prevent the severely atrophic types of paralysis. Vigorous dehydrating measures are recommended during the acute stages.

The prognosis for recovery within six months is usually good, but about 20 per cent of patients are left with residual weakness and atrophy. Medico-legal responsibility in industrial or compensation cases must be recognized.<sup>27</sup> Greater care in the administration of serum when tetanus is suspected and avoidance of the use of antitoxins not of proved specific value will cut down the incidence of these unfortunate complications of biologic therapeutics.

#### CONCLUSION

Complete recovery occurred in three cases and incomplete recovery in two cases of neuritis following horse serum sickness. This distinct clinical entity should be more widely recognized by the medical profession. The present knowledge of the pathogenesis and treatment offers possibilities of prevention.

1204 Medical Arts Building

#### ABSTRACT OF DISCUSSION

DR. WALTER FREEMAN, Washington, D. C. Dr. Bennett has had an exceptional experience in finding five cases in the past six years. The condition occurs relatively often in industrial communities and will continue until the underlying physiology of the serum illness is determined. The theory that the nerves suffer from compression by the swollen tissues is probably the most acceptable one. Here is a difference from certain other kinds of neuritis, for instance the diphtherial neuritis which is often a local condition but which is much more closely related to the site of the injection or the site of the local infection than is the horse serum neuritis. I think Dr. Bennett might emphasize that although these involvements were always in the arm they were by no means always in the arm that was inoculated, whereas in cases of localized wound diphtheria it is the local nerve that seems always to be affected. It is the same way with tetanus itself. Just what the cause of the reaction to this serum is has not been elucidated. While there is a strong element of allergy, the question of blood volume must be considered. If the blood volume is increased beyond the height tolerated by the patient the result is likely to be urticaria. It has been shown by the injection of large quantities of serum and of large quantities even of such an inert substance as acacia. These large quantities can be injected if the person is dehydrated or depleted or otherwise has less than normal blood volume. If he has a normal or a high blood volume, he breaks out into urticaria. The signs of serum sickness resemble those which occur with increased blood volume and they are successfully handled by methods that reduce blood volume. Of those I would emphasize the injections of epinephrine and sweating. These two work rapidly in the reduction of blood volume. Whether Dr. Bennett would like to try hypertonic solution of dextrose on patients with early disease or sweat them right away is a question to be decided later, but certainly the injection of epinephrine in cases in which serum sickness is developing has already been found of great value and I think should be pushed to the limit with patients showing signs of neuritic involvement.

DR. JOHN B. DOYLE, Los Angeles. In the decade between 1920 and 1930 the neurologic literature not infrequently

<sup>26</sup> Examination fifteen months after injury showed residual weakness of the deltoid. The compensation claim was still unsettled.

<sup>27</sup> Wulff<sup>24</sup> Vogel<sup>25</sup> Chavany and Askenazy<sup>22</sup>

described cases of this sort April 17, 1930, I had the opportunity of seeing a man aged 37 who had had a prophylactic injection of serum for scarlatina. Seven days later serum sickness developed. At the height of his pain marked weakness of the right deltoid and scapular muscles developed. Since that time I have had the opportunity of observing two additional cases. Apparently the meninges, the brain, the spinal cord, the nerve roots, the cords of the brachial plexus or the peripheral nerves may be affected. In the majority of cases, however, the brachial plexus has been involved. In a few instances there has been a clinical picture of mononeuritis. Sicard and Cantaloube have offered the explanation that this type of clinical picture is due to edema within the aponeurotic sheath of the affected nerve. To describe the mechanism they coined the term "neurodocitique." In all the cases of involvement of nervous structures associated with the upper limb the disturbance has been of a motor character. In about one fourth there have been additional sensory changes. In the plurality of cases, that is, in thirty of forty-two cases in the series I reported, the involvement was unilateral and purely motor and involved only the fifth and sixth cervical roots or their derivatives. An important clinical point made by Sainton in 1924 is that the process may not involve equally all the fibers of a given muscle but may spare bundles of varying size. This was true in three of the cases which I have encountered. The prognosis is far better than Dr. Bennett might lead us to believe. In his case 3 at the end of a year there was little if any improvement. There are, however, several factors to be considered. First, the patient was not treated at all for five months. During that interval there must have been profound stretching of the muscle. Second, a certain proportion of patient suffering from severe damage may not manifest return of normal sensation until as much as eighteen months has elapsed from the time of onset of symptoms.

DR HYMAN I VENER, Los Angeles. The problem of tetanus is my only reason for any comment regarding this excellent presentation. My experience with several hundred cases has convinced me of the grave seriousness of this disease. The California State Department of Health for the years 1920-1935 reported a fatality rate of approximately 75 per cent for a group of 1,000 cases. It is time the profession took cognizance of the situation. The occurrence of neuritis may be used as an excuse for withholding prophylactic antitoxin. Unfortunately, tetanus cannot be forecast. The apparent innocence of a wound is no criterion of the future result. The disease must be prevented by proper debridement and administration of prophylactic antitoxin. Over many years of active management of clinical tetanus, with an average dose per case of approximately 225,000 units of serum, I have not seen a patient, during hospitalization, in whom this complication developed. Some questions may arise. Was the refining process of the serum faulty? Was the serum used in all cases manufactured by the same biological firm? Could such mishaps have been avoided if the serum had been given intradermally and in divided doses? Is the problem one of individual susceptibility? Progress is being made in the manufacturing process to avoid just such untoward serum reactions. Tetanus toxoid is an excellent product, especially for allergic persons. However, there are too many variable factors to warrant dogmatic statements. Most studies conducted have dealt with adults, whereas the greatest incidence is among children. In man the amount of toxin that will cause clinical symptoms is not known, nor is the duration of immunity conferred known so each case must be judged on its merits. When one is in doubt prophylactic antitoxin should be administered. I hope that the problem will be solved in the near future and the occurrence of such cases as cited further diminished. The comparatively few complications following the administration of prophylactic antitoxin should not deter us from using it. When we consider the thousands of doses used daily for the prevention of the disease which, once it occurs, has an extremely high fatality rate, we must rely on our clinical judgment and exert every possible precaution.

DR HENRY R VIETS, Boston. My experience is based on observation of seven cases, most of them in the last three years. As I remember my war experience, a great deal of horse

serum was given and serum neuritis was rare. My observations on this subject are practically the same as Dr. Bennett's, with one or two exceptions. In the first place, it does not seem to make any difference where the horse serum is injected. In all my cases the principal nerves involved were the fifth and sixth cervical roots and strangely enough, all on the right side. Dr. Bennett, I think, had three on the right and two on the left. Another striking thing is that in not all of my cases was the serum sickness severe. In two cases that I can recall it was slight. That differs a little from Dr. Freeman's report. There is marked atrophy of the deltoid and supraspinatus muscles, in spite of the fact that, in my experience, all patients have recovered almost entirely without any treatment. I have not used the treatment that Dr. Bennett suggests. I feel, therefore, that this syndrome of neuritis limited to the fifth and sixth cervical roots after administration of horse serum is perhaps increasing and it is wise to have a paper of this type before this section so that all physicians will keep this disease in mind.

DR TOM B THROCKMORTON, Des Moines, Iowa. If I recall correctly, the injections in Dr. Bennett's cases followed only small or trivial traumatic conditions, whereas the case which came to my attention some years ago was that of a farmer who, while climbing a ladder into the hay loft, fell, striking on his head and shoulders. He had a slight concussion of the brain and his right hand was injured. He was afterward given the antitetanus and anti-gas gangrene serums, and after this weakness of the shoulder girdle on both sides developed. The question which came up in a study of his compensation was whether the weakness was traumatic as the result of the fall injuring either the spinal cord or, more particularly, the spinal root or whether it was a serum neuritis from which he probably would eventually recover. I saw him within the last year. He has made some improvement, but he still has distinct muscular atrophy of the shoulder girdle on both sides and more particularly on the side on which the infection was more pronounced.

DR LEOPOLD BRAHDY, New York. I have had one case of special interest in connection with this paper. The patient was given prophylactic tetanus antitoxin, paralysis developed on the left side, with left wrist drop, and he made a complete recovery after a few months. Three years later he received a second injection, the paralysis recurred, but this time there was no recovery—the lesion is permanent. I have followed him now for more than three years and there is no improvement. There was a marked alcoholic background in this case and I wish to ask Dr. Bennett to comment on whether an alcoholic basis was in evidence in his cases.

DR L. H. ZIEGLER, Wauwatosa, Wis. This is a timely and interesting study. I have observed two cases similar to those presented by Dr. Bennett in the last two or three years. I should like to present exceptions to the suggestion that the manifestation may be entirely explained by allergy. One often gets off the track when one sticks to a single etiologic concept too tenaciously. The persons who have been given this serum have usually been treated for a wound or some other illness which may have had some relation to the complication. The paralysis sometimes develops in the arm not inoculated. This should make one suspicious that something else may be going on. It is interesting to note that in four of the five cases that Dr. Bennett has presented the onset was in the summer during the poliomyelitis season. I do not mean to imply that this disorder is poliomyelitis. Studies of spinal fluid have not been made and little is known as yet about the pathology of the nervous system. However, there may be some relation to other disorders such as an association of lesions of the nervous system with intraspinal anesthesia and damage to the nervous system from infections such as cowpox. I have a feeling that the explanation for these complications of serum prophylaxis may be due to some unusual local toxin or virus which has some relation to the lymphatic vessels of the peripheral nerves and perhaps the central nervous system.

DR A. E. BENNETT, Omaha. I am glad Dr. Freeman brought out that the reaction is systemic and not local and is not dependent on the site of injection in any way. Dr.

Doyle's remarks about the prognosis, I think, are well taken. I could not determine accurately from the literature the percentage of persons who did not recover. There seemed to be a definite residual group, although many have not been followed long enough to justify certainty of this, and I have not been able to follow enough cases personally to be certain of it. Dr. Vener's remarks concerning the infrequency of complications in treating tetanus were extremely interesting. Under my observation at present is a young woman who, being treated for tetanus, received 300,000 units at the height of her serum sickness, complete transverse myelitis developed almost overnight and she is not going to recover. The condition is permanent with her. It seems to me that there must have been intensive vascular involvement of the spinal cord in this case. I noticed recently in *THE JOURNAL* a report of a case of tetanus treated with 2,000,000 units of tetanus antitoxin. I feel that is an unnecessary amount of serum to be given to a patient. Dr. Viets's experience with cases of mild serum sickness is interesting. I noticed in the literature a few such cases reported. I am glad to hear that all these patients have recovered completely. Dr. Brahdy's observation of a reactivation by a second injection is important. This has been reported a number of times and is in my paper, but I could not bring it out. With regard to Dr. Ziegler's remarks, examinations of spinal fluid have been made in a number of these cases in the early stages. They show increased cell counts and protein contents.

## PRIMARY CARCINOMA OF THE URETER

WITH REPORT OF SEVEN CASES

ALVIN G. FOORD, M.D.  
AND

PAUL A. FERRIER, M.D.  
PASADENA, CALIF.

The rarity of primary carcinomas of the ureter, together with the fact that they are often not even suspected, warrants the presentation of six proved cases and a probable seventh case. Caulk,<sup>1</sup> in his compiled series, together with Hunt<sup>2</sup> and others, found less than 7 per cent of renal tumors primary in the pelvis, while Thomas and Regnier<sup>3</sup> in 253 collected cases of carcinoma of the renal pelvis and ureter found 15 per cent primary in the ureter. These figures suggest that about 1 per cent of carcinoma of the upper part of the urinary tract originate in the ureter.

### HISTORY

Wising and Bliv<sup>4</sup> in 1878 reported the first authentic case with a microscopic diagnosis, an instance of medullary carcinoma with metastasis to retroperitoneal nodes, rectum and perineum. Up to 1900, eight cases had been reported, in all of which the diagnosis had been made at autopsy. Shortly after this, Albarran,<sup>5</sup> Gerstein<sup>6</sup>

and Heresco<sup>7</sup> each made preoperative diagnoses of ureteral tumor by observing a papillary growth projecting from a ureteral meatus. A decade later, in 1912 a diagnostic sign was described by Chevassu and Mock,<sup>8</sup> who called attention to the free bleeding often provoked by the light touch of a ureteral catheter. The first case from the Mayo Clinic was reported in 1921 by Judd and Struthers.<sup>9</sup> In 1924 Kretschmer<sup>10</sup> reviewed the subject and reported a case. In 1930 Rousselot and Lamont<sup>11</sup> were able to collect fifty cases of primary malignant process in the ureter, adding a case. In 1931 Renner<sup>12</sup> reported finding three primary ureteral carcinomas in 13,854 autopsies in five years at the Vienna Pathologic Institute. In the same year Chauvin and Cerati<sup>13</sup> presented a comprehensive study and reported a case. In 1933 Colston<sup>14</sup> reported two cases from 22,000 urologic cases at the Brady Institute at Johns Hopkins Hospital. The first case from the files of the Massachusetts General Hospital was reported by Snyder and Wood<sup>15</sup> in 1933. In 1934 Scott<sup>16</sup> and Lazarus<sup>17</sup> each presented a study and compilation of cases, bringing the total to sixty-eight. Bergendahl<sup>18</sup> of Sweden in the same year presented his summary, with a total of seventy-six cases. In 1936 Schilling and Sondervorst<sup>19</sup> made a thorough study of the literature, presenting two cases and tabulating 113 of cancer of the ureter. In 1938 Rusche and Bacon,<sup>20</sup> reporting two cases, compiled forty of benign and ninety-six of malignant neoplasms. When ten cases not tabulated in any of these summaries (table 1) and our six cases are added, the number of cases of primary cancer of the ureter is 139. Thus in the past eight years eighty-nine cases have been reported, as against fifty in all previous records.

### CLINICAL AND PATHOLOGIC FEATURES

**Age**—The youngest patient was 22 and the oldest 89. There were three in the twenties, seven in the thirties, twenty-six in the forties, thirty-eight in the fifties, forty-four in the sixties, eighteen in the seventies and three in the eighties.

**Symptoms**—The basic triad is hematuria, pain and mass. Hematuria was noted in ninety-seven or 70 per cent, of the 139 cases, in eleven there was no bleeding, and in thirty-one bleeding was not mentioned. The duration of bleeding was under three months in thirteen cases, from three to twelve months in thirteen, from one to two years in four and over two years in nine.

Pain is next in point of frequency (table 2). It occurred in eighty-four, or 60 per cent, of the cases and was noted to be absent in only eleven cases. Its

Owing to lack of space this article has been abbreviated for publication in *THE JOURNAL*. The complete article appears in the authors' reprints.

duration varied from less than three months to many years. It is most commonly a dull ache in the region of the kidney but occasionally a colicky ureteral pain. When the tumor invades the neighboring organs and muscles, pain is constant and sometimes referred to the solar or hypogastric plexus. Extension to pelvic organs causes a perineal ache referred down the legs. Sciatic pain may be severe. Involvement of the bladder may cause intense dysuria. Bone metastasis has its type of pain. In Hunt's case the process metastasized to the brain and was explored as a brain tumor.

The tumor palpated is nearly always the hydronephrotic kidney. It is possible, however, for the kidney to be completely obstructed and not enlarged, as in our first case. It is rarely possible to palpate a tumor of the upper part of the ureter. In our case 4 a tumor of the midureter was palpated, and in cases 2 and 3 a fixed stony mass was felt by rectum above the prostate.

**Urine**—Cases have been reported in which the urine was normal, but red blood cells are probably always present at some time. Pus is generally present, since infection commonly occurs sooner or later. When the growth is papillary, tumor cells or even fragments of growth may be found occasionally.

**X-Ray Examination**—On the flat plate an enlarged renal mass is often distinguishable. Coincident stones may rarely appear, but they seem to have little etiologic significance. Metastases in the lungs and bones should be looked for.

**Cystoscopic Examination**—It is important that this be done while the bleeding is in progress, as a leading point is won by visualizing the bleeding meatus. This was observed in twenty-six of eighty-one cases in which cystoscopic examination was performed (table 3). One should note the character of the jet. Blood from the kidney or upper part of the ureter is likely to be ejected in normal spurts, while a bleeding tumor in the lower part of the ureter will give a feeble spurt, often only a drip. The meatuses may appear entirely normal or there may be congestion or pouting on the affected side. Tumor tissue was observed to project in thirty of seventy-eight cases. The projecting tumor may so obscure the meatus that it is impossible to determine whether it originates in the ureter or at the edge of the meatus. A tumor may peep through the meatus only during ureteral peristalsis, or a telltale bulge may occur at that time. Observation of the ejection of indigo carmine may make more plain the alteration of the peristaltic jet or its absence.

With a great proportion of ureteral tumors there is a complete block, and no catheter or bougie will pass beyond the tumor. This was observed in fifty cases. Chevassu and Mock in 1912 called attention to bleeding through or around the catheter, induced by slight catheter trauma. This was noted in seventeen cases. Of course this is not pathognomonic, since congestion around a stone or a benign lesion may bleed. It is entirely possible for a carcinoma to be present without any bleeding either spontaneous or induced. Marion noted that, while blood might be coming through the ureter, a catheter passing beyond the tumor might drain off clear urine. Blood, however, may retrograde from the tumor to the renal pelvis.

**Urograms**—Excretory urograms usually show no dye in the affected side. They may faintly outline a hydronephrosis or, rarely, show a normal kidney on the affected side. The excretory urogram is inadequate to outline satisfactorily a ureteral filling defect. A catheter

may not enter. It may not be possible, even with a Garceau catheter, to distend the lower part of the ureter. However, with a tight catheter in the lower part of the ureter and the patient in the Trendelenburg position, a gravity flow with the least induction of spasm may give a satisfactory urogram. Serial pyelograms after Moore's<sup>21</sup> method are desirable to show constant filling defects. Clots may cause a false filling defect. Rusche and Bacon obtained a clear picture of a filling defect due to a ureteral tumor by passing a ureteral catheter to the pelvis, drawing it down and injecting at different levels, with a picture of each. Air pyelo-urograms were advocated by Neuwirth<sup>22</sup> in 1924. If the medium passes the obstruction a hydronephrosis is seen with a ureter dilated down to the tumor. If the obstruction is not passed, the medium may distend an atonic ureter. If the catheter does not fit snugly, only a cystogram may result.

The form of filling defect may be (1) a ringlike obstruction, narrow or wide, (2) a single pedunculated or sessile mass or (3) a ragged, moth-eaten condition from papillary involvement, which may extend the whole length of the ureter. The only pathognomonic sign of primary ureteral tumor is a characteristic and constant filling defect, together with a pyelogram excluding renal neoplasm. Periureteral growths, traction and inflammation have not been a source of error. Coincident stone has caused error.

It must be borne in mind that a bleeding papilloma may be so small, no bigger than a grain of wheat, that it produces no obstruction to a ureteral catheter, no filling defect, not even a palpable mass when the ureter is exposed surgically. If a nephrectomy has been done for bleeding and the kidney does not explain the source prompt ureterectomy is indicated unless benign ureteral disease is demonstrated. Many operations have been done with the expectation of finding a renal neoplasm. At a second operation the ureteral cancer was removed. Peacock<sup>23</sup> recently reported a case in which another

surgeon had removed the kidney, leaving a ureteral tumor, which by delay had become inoperable Table 4 summarizes the diagnoses made in the reported 139 cases

*Pathology*—In the cases so far reported, the lower end of the ureter has been by far the commonest place for the tumor to appear, eighty-five of the tumors having been located in the lower third, twenty-three in the middle third, twenty in the upper third, six in the

entire ureter, two in the middle and lower thirds and one in the upper and middle thirds No location was given in two cases All degrees of involvement of the ureter from small localized lesions to massive involvement of long segments have been reported, in many cases one third or more of the ureter was involved Because of marked differences in the terminology used, it is difficult to classify some of the tumors accurately However, the tumors closely resembled those in the bladder, and, of the 139 reported, seventy-five were papillary, sixty were some type of solid, nonpapillary tumor, three were reported as adenocarcinoma and one was unclassified There is insufficient evidence for us to agree with the authors who reported the adenocarcinoma Small papillary growths mentioned here and there in the literature are often classified as benign tumors, but none of these are included in our summary of the literature However, from experience with tumors of the bladder, we feel that these should be considered as low grade malignant processes, since recurrence is such a common clinical experience

A satisfactory grouping is as follows

1 Papillary carcinoma

(a) The so-called single pedunculated papilloma, sometimes called benign

(b) The single pedunculated solid appearing carcinoma which distends and blocks the lumen Such carcinoma show microscopically some papillary structure

(c) The single papillary carcinoma with a sessile invaded base

TABLE 3—Cystoscopic Data

Number of cases studied	81
Ureteral tumor visible	30
Ureteral tumor visible only during peristalsis	2
Bleeding from meatus	26
Congested meatus	7
Impassable obstruction to catheter	50
Catheter trauma (Chevassu and Mock)	17
Blood from meatus clear urine from catheter above tumor	3
Associated tumor of bladder	6

(d) The diffuse papillary carcinoma showing multiple growths, often extending nearly the entire length of the mucosa of the ureter Such carcinomas may or may not thicken the underlying wall very much

2 The solid, nonpapillary carcinoma which begins as a localized lesion This may continue as a localized diffuse thickening of the wall, but it commonly grows so as to thicken markedly the wall and involve its entire circumference It is notoriously invasive and spreads commonly for considerable distances in the wall of the ureter and often into neighboring tissues

It is possible that, as in the bladder, the tumor may start as a papillary growth which invades the underlying wall, the superficial papillary portion may slough away because of interference with the blood supply, and the remaining tumor may be considered a solid, nonpapillary invasive tumor when seen with the naked eye

Many histologic classifications are given in the literature, but a simple classification similar to that used for cancers of the bladder appears most satisfactory The tumors can therefore be classified as papillary and nonpapillary growths and the latter graded numerically as squamous cell neoplasms according to Broders' classification On the whole, the cancers reported have shown approximately the same histologic patterns and the same degrees of malignancy as would be expected in a series of cancers of the bladder

TREATMENT

All authorities agree that the treatment of choice is early surgical extirpation, which means nephrectomy and ureterectomy

For forty-four nephro-ureterectomies in one stage the mortality was 40 per cent, while for twenty-two nephro-ureterectomies in two stages the mortality was 5 per cent

If a certain diagnosis has been reached, preoperative roentgen treatment is justified Postoperative roentgen treatment is of some value, particularly to relieve the pain of extension and metastasis

PROGNOSIS

For a total compiled series of 100 operations, the three month mortality was 34 per cent Scott in 1931, in an effort to follow collected cases in which operation was performed, could find only two patients alive after five years One patient reported on by Kraft Vorpahl's 33 patient lived eight years after a nephrectomy and partial ureterectomy and died with general metastasis The growth was squamous Crance and Knickerbocker 34 reported that a patient was well eight years after a nephro-ureterectomy for a nonpapillary cancer

In general the early and the late prognosis are very unfavorable

REPORT OF CASES

Pathologic studies, including surgical and postmortem examination, were done by one of us (A G F) in all the cases except case 6, which was

provided by Dr Newton Evans and Dr C B Coggin Urologic studies, by one of us (P A F), were performed only in cases 1 and 2

CASE 1—Mrs I M J, white, aged 69 who entered the Huntington Memorial Hospital Feb 27, 1934 had first noted painless hematuria one year before, with complete remission for five months. It recurred and continued in severe form. The hemoglobin content dropped to 66 per cent (Newcomer)

Fig 1 (case 1)—Ureteral wall showing nests of poorly differentiated squamous cells invading widely

She lost 20 pounds (9 Kg) and looked ill. The heart and lungs were normal. The blood pressure was 130/70. The urine showed gross blood, a few pus cells and casts. In the phenolsulfonphthalein test 15 per cent was excreted the first hour and 15 per cent the second hour. Roentgenograms of the kidneys, ureters, bladder and lungs were normal. An intravenous urogram showed a normal left renal outline and no shadow on the right. Cystoscopic examination showed blood trickling from a relaxed right meatus, without spurts. Otherwise the results were negative. No tumor protruded. Indigo carmine was excreted heavily on the left and not at all on the right. Catheters on the right side met with an impassable obstruction below the brim of the pelvis and caused increased bleeding. A ureterogram showed a relaxed right ureter completely obstructed just below the pelvic brim. There was no irregularity of the wall.

The diagnosis was tumor of the right ureter possibly secondary to renal tumor. Through curved loin and right rectus abdominal incisions a right nephro-ureterectomy was done. The tumor was limited to the middle third of the ureter and was adherent to the fascia surrounding the common iliac vessels. The iliac and para aortic vessels were not indurated. As the growth was obviously squamous and not papillary, the mural ureter was not removed. No radiation was given.

The patient lived comfortably for over a year then began to have sciatic pain on the right side and pain in the chest and she died with metastases in the liver and lungs as shown by a nodular liver and a roentgenogram of the chest. No autopsy was performed.

The pathologic specimen consisted of a right kidney and 22 cm of ureter. A segment of ureter 2 cm long beginning at a point 14 cm from the pelvis was thickened to 1.2 cm in external diameter and on section gray homogeneous fairly firm tumor tissue was seen to fill the lumen and to invade the wall. Dilatation of the ureter to 1.5 cm in circumference with moderate thickening was noted above the tumor. Numerous small dilated veins were seen in the mucosa just below

the tumor. Marked simple hydronephrosis with fibrosis and atrophy of the parenchyma, so that it was only 12 or 13 mm thick was present in the kidney, which measured only 9 by 5 by 3 cm.

Microscopic examination showed the tumor to be a solid, nonpapillary, poorly differentiated (grade 3) squamous cell growth (fig 1) arising from and replacing the mucosa and infiltrating the entire wall in various-sized nests, about which moderate fibrosis was present. The tumor cells were medium sized, noncornified squamous cells varying much in size and shape and showed many mitotic figures. Portions of the ureteral epithelium not involved by the tumor showed slight squamous cell metaplasia. The kidney showed simple hydronephrotic atrophic and fibrotic changes.

The diagnosis was solid, nonpapillary, poorly differentiated squamous cell carcinoma (grade 3) of the lower end of the ureter, 8 cm from the bladder, with complete obstruction, moderate hydro-ureter and marked hydronephrotic atrophy and fibrosis of the kidney.

CASE 2—J L, a white man aged 82, who entered the Huntington Memorial Hospital March 4, 1938, claimed that he had had good health up to one month previously, when he began to have vague abdominolumbar pain on the left side with gross hematuria and loss of weight and strength. Ten years previously a benign prostatic growth had been removed suprapubically. There was fullness without tenderness in the left renal fossa. The prostatic bed was firm and above it on the left was a hard, fixed mass. The blood pressure was 160/80. Roentgenograms of the kidneys and bladder showed nothing abnormal except ill defined density in the left renal area. An intravenous urogram showed a normal right side but no dye on the left. Cystoscopic examination with spinal anesthesia showed the bladder neck high and fixed. Many clots were evacuated. The right meatus appeared normal but the left could not be visualized on account of a tumor mass which seemed to elevate the floor of the bladder on the left and to invade it as a mass 2 cm in diameter where the meatus should have been. Biopsy showed an invasive squamous tumor consistent with vesical or ureteral origin. A diagnosis of cancer of the ureter was made.

Bleeding was controlled by coagulation, but the next day the bladder was again filled with clots. After transfusion the left kidney and 16 cm of the ureter were removed. The kidney was greatly distended with clear urine. The tumor of the

Fig 2 (case 2)—Wall of ureter showing papillary portions and areas of squamous cell differentiation

ureter extended from the pelvic brim underneath the bladder so extensively as not to be operable even to stop hemorrhage. Despite coagulation hemorrhage continued and the patient died six days later.

The surgical specimen showed by gross and microscopic examination a simple profound hydro-ureter and hydronephrosis with atrophy and fibrosis of the renal parenchyma. The ureter averaged from 23 to 28 mm in circumference. The kidney measured 11 by 5.5 by 3 cm.

be more slowly secured. The transduodenal method is carried out with too little inconvenience to the patient or consumption of time for the physician to persuade one to trade a reasonably certain method for a doubtful one.

In no case has freedom from worms been recorded on the evidence of normal stools alone, it is insisted that examination of the duodenal fluid must repeatedly show negative results. It is believed that at least some of the cases reported in the literature as instances of rid-dance of worms would not have been so classed had duodenal drainage been done.

#### MOP-UP CAMPAIGN

My experience convinces me that riddance of infestation is not assured unless a thorough systematic cleaning-up program is instituted. The carpets and rugs must be either dry cleaned or exposed to the sun's rays for several days. Wearing apparel not damaged by heat should be boiled, other garments should be dry cleaned. Floors should be scrubbed with soap and hot water. The floors of cellars and outbuildings, if earthen, should be covered with lime, if wood they should be scrubbed with soap and water. Household pets, dogs and cats, should be either killed or treated. Examination of the

water supply has shown no ova in my experience. Examination of every member of the family should be searchingly done. It does not seem reasonable to conclude that the family will escape after one member becomes infested.

#### REPORT OF CASE

*History*.—A single woman aged 33, born and reared on a farm, had the usual diseases of childhood without complications, and at 19 appendicitis with rupture before operation and a slow convalescence covering some twelve months. The menses began at 13 and continued normally. Her maximum weight was 128 pounds (58 Kg) at 25, her current weight ranged from 98 to 100 pounds (44.5 to 45.4 Kg).

She was seen in consultation with Dr J. C. Hartman, the family physician, and Dr Lamar Neblett, surgeon, having been admitted to St Anthony's Hospital with a tentative diagnosis of "surgical abdomen." She had been ill for one year, with a poor appetite, nausea, occasional vomiting, unlocalized pain in the abdomen, abdominal distention and tenderness of a low grade, loss of weight and strength, a tendency toward constipation and an almost daily headache.

*Examination*.—She appeared undernourished with dry, atonic skin and flaccid muscles. There was low grade cervical adenopathy. An adenoma was present at the junction of the isthmus and the left lobe of the thyroid. The lungs showed no active abnormality. There were no neurologic signs of diagnostic significance. There was a marginal infection of the gums, and the tonsillar crypts contained cheesy exudate. Generalized abdominal tenderness was present, most marked in the lower part of the epigastrium and below the umbilicus, the liver was not palpable, but there was low grade tenderness on heavy percussion. The cecal head was palpable and tender,

the sigmoid flexure, spastic and tender. Peristalsis was audible and accentuated by palpation. By percussion the spleen measured 8 by 9 cm.

Urinalysis showed no abnormality except an occasional hyaline cast. A blood count showed 4,200,000 erythrocytes, 14,800 leukocytes and 85 per cent hemoglobin, the color index was 1, and there were 62 per cent polymorphonuclears, 24 per cent lymphocytes and 14 per cent eosinophils. The results of fractional gastric analysis after a test meal are shown in the accompanying table.

The duodenal contents showed *Strongyloides* larvae (motile) and adult worms, the feces (obtained by saline purgation), *Strongyloides* (actively motile) and occult blood.

*Clinical Course*.—Thymol, carbon tetrachloride, santal, oil of chenopodium, dihydranol and gentian violet were used in turn. With some the duodenal contents showed a disappearance of larvae for a few days only, with as many appearing at subsequent study as before treatment. Observations were made in the laboratory to determine the killing strength of some, in fact most, of these chemotherapeutic substances. Solutions of salicylic acid (1:100) lessened motility definitely, but complete cessation was not obtained if the specimen was kept on a warm stage. Iodine was then tried, and an almost spectacular change was noted in less than one minute. The worm would rapidly lose motility and straighten out and could not be restored. There was little difference in effectiveness between tincture of iodine and compound solution of iodine. The latter was selected for use. It was given through a transduodenal tube. Larvae recovered from the duodenum and in the feces were motionless and eventually determined to be lifeless. This proved only a temporary disappearance, however, as larvae were recovered when the patient returned in two weeks. The term temporary disturbance is emphasized for in this patient and four other members of her family adult worms and larvae were again found in two weeks. Only after a thorough clean up campaign, followed by a course of compound solution of iodine given by tube were permanent negative results charted.

The patient gained weight, from 105 pounds (47.6 Kg) on discharge from the hospital to 129 pounds (58.5 Kg) in April 1936.

#### SUMMARY

Strongyloidiasis is a more frequent infestation than the profession appears to believe.

Its diagnosis rests ultimately on the finding of parasites or larvae in the duodenal contents and feces.

Iodine has been found the most satisfactory agent for removal of the worms.

A series of nine cases were studied as a basis for the conclusions reached on the efficacy of treatment.

The criteria on which the conclusion of permanent riddance of infestation was based were repeatedly negative results of study of the duodenal fluid and feces.

#### ABSTRACT OF DISCUSSION

DR THOMAS T. MACKIE, New York. Dr Simpson did not have time to discuss certain important aspects of the life cycle of this parasite. The adult female penetrates the mucosa of the intestine, often creating extensive tunnels in the host tissue. These are superficial to the muscularis mucosae. Viable larvae are produced which usually are passed in the stools as the rhabditiform or noninfective form. The infective filariform larvae may likewise be produced in the host's intestinal tract. These invade the tissue, are transported to the lungs by the blood stream and ultimately reach the intestine by way of the esophagus and stomach when they grow to maturity. There is therefore the possibility of continuous hyperinfection. A parasite capable of producing such anatomic changes in the intestinal mucosa from duodenum to rectum may be responsible for disease. Unfortunately, most if not all of the studies of the clinical significance of this parasite have been insufficiently controlled. Persons harboring the *strongyloides* have necessarily been exposed to infection by numerous other intestinal parasites, helminthic and protozoal, to say nothing of bacterial. I have seen many

infected persons in Central America. Without exception they presented mixed infections, harboring in addition ascarids, hookworms and various types of protozoa. I have not seen intestinal disease which could with certainty be ascribed to strongyloides infestation. It is highly important to continue the clinical studies of this infection. They must be controlled by complete studies of the helminthic and protozoal load and by cultures for pathogenic bacteria. Although I do not feel competent to discuss therapy of this infection, it is relevant to point out that certain combinations of iodine are relatively efficient amebicides.

## MANAGEMENT OF PROSTATIC DISEASE IN PERSONS PAST 75

A REPORT OF SEVENTY-FIVE CASES WITH  
END RESULTS

ALF H. GUNDERSEN, M.D.

LA CROSSE, WIS.

In a recent paper read before the Wisconsin Urological Society on transurethral prostatic resection for bladder neck obstruction, I discussed the general problem of prostatic disease. I also carefully analyzed 100 consecutive cases of resection and compared them with 100 cases of total enucleation. The mortality rate was a flat 2 per cent for the resection group, and, remarkably enough, the two deaths occurred in relatively young men, aged 61 and 65, respectively. There were no deaths among the fifty-two patients over 70. This was encouraging and argued strongly for resection for the aged person with prostatic disease, particularly in view of the repeatedly proved fact that the mortality in any enucleation group rises sharply after the age of 70 (in my series of 100, up to 18 per cent).

The very aged, who formerly preferred either to carry on with their suffering or, in many cases, to continue with catheterization, are now seen in the urologic wards of hospitals as willing patients, electing resection rather than continuance of the uncomfortable and oftentimes painful existence which inevitably led to death. The surgeon who formerly refused to operate on the aged because of the grave risk involved with prostatectomy is now confident of his ability to benefit that group through transurethral resection. As time has gone on, with subsequent improvements of technique and armamentarium and shortening of operating time, the courage and confidence of the resectionist have increased.

During 1937 I had a relatively large group of the very aged, the total being thirty-two patients over 75 years of age. The results were so uniformly satisfactory that I was prompted to analyze them in detail, particularly in view of the fact that there was only one death in the group. The analysis brings home more forcibly than ever the fact that the experience of the operator is by far the most important factor in obtaining good results with transurethral resection. Not only was there but one death in this group in 1937, but the end results were uniformly more successful and the complications more rare. For the entire series of seventy-five patients the average age was 79½ years, 35 per cent were past 80, and two were past 90.

During the early period of transurethral resection there was apparently a great deal to be learned. It became evident that the total operating time had to be cut down. To subject a man of 80 to one hour of

urethral trauma is entirely too much. One should strive to operate rapidly and to finish the entire resection in from forty to fifty minutes. Loss of blood weakens the aged rapidly. A supportive transfusion shortly after the operation is helpful in combating shock. This is resorted to more frequently now than in the past. In the 1937 group 70 per cent had one or more transfusions. Adequate continued control of bleeding throughout the operation is of great importance.

Flocks's<sup>1</sup> and Alcock's contributions to our knowledge of the blood supply of the hypertrophied prostate have been used to advantage in operative technique. By cutting downward deeply at 7 o'clock and at 5 o'clock to the floor of the bladder, one is in a position to fulgurate the large feeding arteries to the subcervical portion and the middle lobe of the hypertrophied gland. The remaining intravesicular projections, except the anterior lobe, then become relatively avascular. In my experience the most difficult hemorrhage to control is that which occurs at the apex of the prostate, near the verumontanum. Cutting here is deferred until the very last of the operation, after all other bleeding is stopped. Occasionally in my efforts to make lateral excavations I have cut into the surgical capsule of the prostate. In so doing one may encounter large venous sinuses which are extremely difficult to control, in fact, on two occasions recently I could not stop the bleeding by coagulation. With this type of hemorrhage a traction bag is invaluable. The slightest traction on the bag will promptly stop the bleeding. This adjunct to the urologist's armamentarium has doubtless saved many lives. The new 5 cc retention type of catheter has done away with adhesive tape fastenings. It permits free drainage of urethral pus incident to the presence of the catheter. Its use has become a routine.

As I pointed out in a previous paper the irrigating fluid at the end of the operation must come back clear or a very very pale pink. Bleeding will only obstruct the catheter and disturb the entire convalescence. Irrigations of the catheter have rarely been necessary in my experience but must always be resorted to immediately by a trained attendant if a clot obstructs the eye of the catheter. Constant uninterrupted drainage of the catheter is by far the most important single item in convalescence.

Adequate removal of all obstructing tissue is a cardinal factor of success in the management of prostatic obstruction. It is even more important with the very aged than with the younger person. Inability of the urine, usually infected, to pass freely over the cut surface of the posterior portion of the urethra leads not only to severe toxemia but frequently to sepsis and disaster. Inadequate removal necessitates a second resection in an already weakened person, which is frequently the straw which breaks the camel's back. Every effort should be made to complete the operation in one sitting. The second resection is often poorly tolerated and when necessary must be undertaken only when the patient is afebrile and definitely on the mend, not when he is going downhill. If the patient is unable to void freely, it may mean that the operator has overlooked hypertrophy of the anterior lobe. This is best diagnosed with the retrospective lens, the use of which is important to successful resection. However, obstructing tissue projecting into the very outlet of the created

<sup>1</sup> Flocks, R. H. The Arterial Distribution Within the Prostate Gland. Its Role in Transurethral Prostatic Resection. *J. Urol.* 37: 524 (April) 1937.

funnel near the verumontanum may also be overlooked. These obstructions result from undermining of the lateral lobes with the loop and failure to remove the prostatic tissue high in the lateral lobes low down in the posterior portion of the urethra. When the catheter is removed, they fall downward into the apex of the cone. In my early experience, for fear of injuring the external sphincter I made this error frequently. Hyperplastic prostatic tissue in cases of large adenoma may bulge into the posterior part of the urethra from the lateral lobes, even after what appears to be a large and adequate resection (from 30 to 50 Gm). As Flocks<sup>2</sup> has shown, such hyperplastic masses have been deprived of their main source of blood, the intra-urethral arteries. They not only cause partial or complete obstruction but are a common cause of continued sloughing, infection, urinary frequency and sometimes encrustations. Healing and epithelization of such bulging tissue masses is necessarily slow and accounts for many of the poor results and delayed healing. If one is to be successful, one must be radical, bearing in mind that in results the perfect resection approaches complete transurethral prostatectomy.

As I pointed out before, I make every effort to carry out an aseptic technic in the preoperative, operative and postoperative care of the patient with prostatic disease.

I am convinced that the careless introduction into the obstructed bladder of an aged man of foreign organisms to which he has no immunity is dangerous. Particularly is this true when the bladder and the posterior part of the urethra are severely traumatized as they are by transurethral operations, when relatively ineffective drainage by catheter is used. I have no proof that an aseptic technic speaks for less severe reactions and the avoidance of pyelonephritis, because so many other factors are involved in the evaluation of results, but the rationale is sound.

It had long been my routine to place all prospective subjects for resection on methenamine and ammonium chloride on entry to the hospital. In June 1937 I changed to sulfanilamide as a routine drug. Each patient is given 40 grains (2.6 Gm) each day with sodium bicarbonate and the drug is given throughout the preoperative and immediate postoperative period. If symptoms of toxemia, such as languor, lassitude, cyanosis, weakness, tinnitus, chills and fever, set in, the drug is withdrawn. It is sometimes difficult to differentiate between fever caused by trauma and infection in the urinary tract and fever caused by the administration of sulfanilamide. If the fever is caused by the drug alone, the temperature usually subsides within twenty-four hours after the withdrawal of the drug. I have not yet any definite proof with regard to the value of sulfanilamide as a prophylactic drug against infection following transurethral operations, but I am of the distinct impression that the patients do better, the margin of safety seems greater, the reactions less severe and the incidence of pyelonephritis less. The drug has been found of distinct value late in convalescence in clearing up infection after sloughing has stopped. Other observers, however, reporting large series of cases, have found sulfanilamide of no value as a prophylactic drug against infection and sepsis.

There is still some controversy with regard to preoperative drainage. In the presence of impaired renal function caused by back pressure, improvement after drainage is spectacular and must be carried out before resection is attempted. Furthermore, in the presence of infection with fever, drainage must be instituted. Indiscriminate catheterization or allowing a catheter to remain in the urethra can only do harm to the patient with good kidney function. It has been shown by Cabot and Meland<sup>3</sup> that after a catheter has remained in the urethra there comes a time, usually on the fifth or seventh day, when it often serves to irritate and aggravate the usually low grade infections commonly present in the hypertrophied glands of old men. The patient begins to have fever and becomes mildly toxic. It soon became evident that the patients with good kidney function who had never been catheterized did much better than similar patients in whom drainage with a urethral catheter had been done. Resection carries with it little shock to the cardiorenal mechanism and therefore can be performed without drainage in the majority of cases (in this series of seventy-five, or 66 per cent).

A patient who has had a large distended bladder for a long period, with elevated values for the blood chemistry, must have slow decompression, but, as Thompson has pointed out, resection can be performed successfully on patients with highly elevated values for the blood chemistry provided the daily output is abundant and the nitrogen retention products are reasonably stabilized.

One must always remember that aged persons never do well if convalescence in bed is prolonged. My patients remain in the Fowler position four hours after the operation and are out of bed the following day. On the day of removal of the catheter (second or third) they are encouraged to walk about. They must be made to eat, brandy and nourishing fluids are of value. Often if the patient starts going downhill, the battle is lost, again transfusions must be resorted to.

#### ANALYSIS OF SEVENTY-FIVE CASES

An analysis of the cases shows that in 92 per cent the involvement was primary while in 8 per cent it was recurrent. Three recurrences followed a Caulk cauterization procedure elsewhere, two followed resection elsewhere, and one followed perineal prostatectomy in 1919, suprapubic enucleation in 1924 and finally, after complete obstruction, transurethral resection in 1935.

Preoperative complications were not unusual. Thirty-nine per cent of the patients showed symptoms of uremia with elevated nonprotein nitrogen levels, 67 per cent had grossly infected glands without fever, 22 per cent had infected glands with fever and 11 per cent had clean glands. 32 per cent of the patients came to the hospital with complete obstruction, and 66 per cent were operated on without preliminary catheter or suprapubic drainage.

Microscopic section showed 27 per cent of the lesions to be carcinoma. The average stay in the hospital for all cases was sixteen days. The average amount of tissue removed was 15.08 Gm. Seventy-two per cent of the patients had one resection and 23 per cent two resections.

<sup>2</sup> Flocks, R. H. Local Repair Following Transurethral Prostatic Resection. Its Role in the Clinical Events Associated with This Operation. *J. Urol.* 40: 208 (July) 1938.

<sup>3</sup> Cabot, Hugh and Meland, E. L. The Problem of Drainage in Preparation for Operations for Prostatic Obstruction. *Proc. Internat. Assemb. Inter State Post Grad. M. A. North America* 1932.

Operative and postoperative complications were common during the first three years of my experience. In four cases of hemorrhage reoperation was required for control of bleeding.

The immediate hospital mortality rate was 53 per cent (four patients). One death was due to perforation of the bladder (seen post mortem), one to bronchopneumonia on the tenth postoperative day (seen post mortem), one to pyelonephritis six weeks after operation (seen post mortem).

Eight patients died within one year after leaving the hospital, three of them had carcinoma and died of cachexia. Heart disease claimed two patients, and carcinoma of the stomach and bowel caused the death of the remaining three of this group.

Nine patients have since died of varying causes. Satisfactory function of the bladder was obtained in all cases of this group.

#### Summary of Fifty-Four Questionnaires

1. Are you satisfied with the present condition of your bladder?

51 answered yes

3 answered no { 1 incontinent  
1 partially incontinent  
1 with frequency

2. Does the urine flow freely?

51 answered yes

3 answered no { R Operation 1936  
S Operation 1937  
G Operation 1935

3. How many times do you get up at night?

4 omitted to answer

6 answered not at all

44 answered average 2.4 times

4. Is urination painful to you?

46 answered no

5 answered yes

3 answered slightly { 1 benign disease  
2 carcinoma

5. Is your general health improved since operation?

40 answered yes

2 answered no (carcinoma)

12 omitted to answer

6. Have you gained or lost weight since operation?

2 answered lost

17 answered same weight

28 answered gained (average 15 pounds [6.8 Kg])

7 omitted to answer

Fifty-four of the seventy-five men are still living. Each was sent a questionnaire, and, remarkably enough, answers were obtained from each patient. These are shown in the accompanying table.

#### CONCLUSIONS

A satisfactory result with the aged patient with prostatic disease depends largely on the skill and experience of the operator. Urethral trauma must be minimized by shortening the operating time, hemorrhage must be under control at all times. Supportive blood transfusions should be given more frequently than to younger patients (70 per cent of my group in 1937 received one or more transfusions). Whenever possible, the entire obstruction should be removed in one sitting, a second resection is often poorly tolerated. Asepsis, adequate removal of all obstruction and meticulous care of the draining catheter are even more important in older than in younger patients. I believe that sulfanilamide as a preoperative prophylactic drug against infection is of value. Despite the fact that men over 75 with prostatic obstruction are a precarious lot, resection does hold for them relief from suffering and a comfortable life so far as the bladder is concerned. There will always be a mortality rate, but with care and proper management it can be kept surprisingly low.

## Clinical Notes, Suggestions and New Instruments

### RECURRENCES OF UNDULANT FEVER (BRUCELOSIS) FOLLOWING THE ADMINISTRATION OF SULFANILAMIDE

W. TURNER BYNUM, M.D., CHICKASHA, OKLA.

Within the past year ten articles in the American and British literature have come to my attention, all reporting uniformly good results in the treatment of undulant fever with sulfanilamide, no case of failure having been recorded. Because of this, and because of the unusually small number of cases reported in any series, along with the danger of the indiscriminate use of this remedy and the belief that a word of warning should be voiced to prevent the overenthusiastic employment of this procedure, I report six cases which have been unsuccessfully treated with large doses of this drug as described in the aforementioned articles.

#### REPORT OF CASES

CASE 1—A white man aged 28 entered the clinic May 3, 1938 complaining of chills, fever, fatigue and aching in the lower part of the back and the calves of both legs.

The patient was a dairy worker and stated that it was his custom to "clean up" the cows, without the use of rubber gloves, after they had aborted, he had carried out this procedure several times during the past year, the last time being about April 1. He also stated that he had drunk a good deal of milk given by infected cattle.

For the two weeks preceding entrance he had had chills and fever at irregular intervals of from twenty-four to forty hours. For the past week he had been unable to perform his duties because of marked weakness, aching and fever.

The patient was fairly well developed, he was lying quietly on the examination table, mentally alert and cooperative. The temperature was 98.2 F, the pulse 84, the blood pressure 114 systolic 80 diastolic. He weighed 155 pounds (70 Kg). The skin was moist and warm. The eyes and ears were normal. The mouth showed evidence of oral neglect with pyorrhea of several teeth. The tonsils were submerged and cryptic, the pillars were not injected. The thyroid was not palpable. The heart and lungs were normal on auscultation and percussion. The abdomen was normal. The reflexes were physiologic. The extremities were normal.

At 4 p. m. on the day he was hospitalized the patient experienced a chill and his fever mounted to 103.8 F and returned to 99 F at 10 o'clock.

Laboratory examination revealed the following: The red blood count was 4,320,000, hemoglobin content 14 Gm, white blood count 5,100. The Kahn reaction was negative. The sedimentation rate was 7 mm in one hour. Undulant fever agglutination was 4 plus in all dilutions to 1:480. The tuberculin reaction was negative with purified protein derivative. The cutaneous test was markedly positive to 60,000 Brucella abortus and Brucella melitensis organisms.

Following a second chill and fever to 103 F the patient was placed on sulfanilamide and given 450 grains (30 Gm) in eleven days, as follows: first day 60 grains (4 Gm), second, third and fourth days 80 grains (5 Gm), fifth day 60 grains, sixth day 40 grains (2.6 Gm) and then 10 grains (0.65 Gm) for five days. The temperature became normal and the patient felt markedly improved on the fourth day. He continued to improve and had no further fever for five weeks, at which time he had a chill and was reported to have a fever as high as 105 F. Following this he had a return of chills, fever, malaise and aching recurring at irregular intervals as before. He was again placed on sulfanilamide as previously, which was likewise accompanied by a remission of symptoms on the fourth day. Immediately after his course of sulfanilamide he was given atabrine 5 grains (0.3 Gm) three times a day for five days on the advice of another physician. Following this the patient was not heard from for three months, but inquiry at this time disclosed that he had recently had a return of his symptoms and was at that time "taking treatment" from an Indian faith healer who "had his temperature down one degree."

CASE 2—A white man aged 26 was brought to the hospital June 4, 1938, in a delirious state and with a temperature of 105 F. The history given by relatives at this time disclosed the following significant facts. The patient had recently been on a fishing trip in an endemic malarial country and had been drinking much milk from a cow known to be "Bang positive."

On physical examination the patient was asthenic, irrational and thrashing about in bed. The blood pressure was 142 systolic, 70 diastolic, the pulse was 126, the temperature 105 F, the respiratory rate 18. The examination was otherwise essentially negative. Laboratory examination revealed red blood cells 4,850,000, hemoglobin 14.5 Gm, white blood cells 8,250. The sedimentation rate was 6 mm. The Widal reaction was negative. Thick smears taken at the height of fever were negative for malarial parasites. The Kahn reaction was negative. Undulant fever agglutination in dilutions of 1:60 was 4 plus, of 1:120 4 plus, of 1:240 3 plus and of 1:480 2 plus. The cutaneous test was markedly positive for undulant fever. Roentgenograms of the chest were negative.

After three days, with two subsequent chills and intermittent fever to 103.2 F, a diagnosis of undulant fever was made and the patient was given sulfanilamide 450 grains in six days, then 20 grains (13 Gm) a day for five days and 10 grains a day for one week.

The patient had chills and fever for three days following institution of treatment and continued to have an intermittent but gradually diminishing daily elevation of temperature of about 2.5 degrees F for seven days. At this time it was found that the patient's hemoglobin content was reduced to 11.5 Gm and a transfusion of 550 cc of whole citrated blood was given and medication was continued.

The patient apparently made an uneventful recovery gained weight and felt well for three weeks after discontinuance of treatment, then there was a return of symptoms of intermittent fever, anorexia and weakness. The patient was advised to take vaccine treatment which he did for two weeks but discontinued this because of his belief that vaccine was aggravating the condition.

CASE 3—A nurse aged 23 consulted me July 2, 1938 because of 'waves' of mental depression, malaise and fever to 100.5 F, which had occurred at irregular intervals of from two to four days for six weeks. The patient was known as a 'great milk drinker' and had drunk milk from a number of different sources, some raw, but none known to be from infected cattle.

The patient was well nourished, plump and alert. The temperature was 100 F, the pulse rate 96 and the blood pressure 106 systolic, 70 diastolic. The mouth was well kept with tonsil tags at both bases. The heart, lungs and abdomen were normal. Pelvic examination was essentially negative. The red blood cells numbered 4,200,000, the hemoglobin content was 14 Gm and the white blood count was 4,680. Undulant fever agglutination was 4 plus in all dilutions. There was a markedly positive cutaneous reaction with 5,000,000 *Brucella abortus* and *Brucella melitensis* organisms. The percutaneous tuberculin reaction was mildly positive. X-ray examination of the chest was negative. The patient was given 450 grains of sulfanilamide in ten days, 350 grains in the first five days. She continued her duties but malaise and aching persisted, although she had a remission of fever after the seventh day. The fever returned eighteen days after discontinuance of treatment and continued for ten days, when the patient was placed on vaccine treatment in very small daily doses, which frequently gave marked local and mild general reactions, but she was markedly improved after two months of continuous treatment by vaccines and has remained free from fever to date, Nov 7, 1938.

CASE 4—A white woman aged 38, a nurse, consulted me July 18, 1938, complaining of alternating periods of exhilaration and depression 'waves' of fatigue and anorexia, associated with pain and swelling in the middle and ring fingers of the right hand and some rather vague generalized aches and pains throughout the body of four or five months duration. The patient lived in a district where Bang's disease was prevalent, had drunk milk from many sources but had had no direct contact with infected cattle.

On physical examination the temperature was 99.6 F, the pulse rate 60, the blood pressure 100 systolic, 70 diastolic, but

examination was otherwise essentially negative. Laboratory examination August 17 revealed the sedimentation rate to be 12 mm, hemoglobin 16 Gm, red blood count 5,600,000. Gastric analysis revealed free hydrochloric acid 12, total acid 28. Undulant fever agglutination was negative. The basal metabolic rate was plus 5 per cent. X-ray examination of the chest, stomach and colon was negative and of the right hand revealed evidence of periostitis of the affected fingers. The intracutaneous tuberculin test gave negative results. The intracutaneous test for undulant fever with 60,000 *Brucella abortus* and *Brucella melitensis* organisms gave the largest reaction that I ever observed with a like amount of vaccine, the redness and induration extending from the cubital fossa to within 2 inches of the flexor surface of the wrist and persisting in this condition for ten days following which a suppurating abscess formed which drained for eight weeks.

The patient was seen in consultation by three other physicians and a diagnosis of undulant fever was agreed on and sulfanilamide therapy instituted August 17, 380 grains (25 Gm) being administered in five days and 10 grains a day for ten days. The patient was last seen October 15, at which time she stated that she had noted no improvement in her general condition had continued to have subjective symptoms but was more interested at the time in a lump in the breast for which surgery was advised, but the patient has not been heard from since.

CASE 5—Dr H. M., a man aged 34, an associate of mine, had been complaining of recurrent transient attacks of fatigue, anorexia, depression, somnolence and generalized aching lasting from a few hours to two days and recurring at irregular intervals for several months and associated with a sensation of fever.

The patient was robust with no physical abnormalities, having a temperature of 99.8 F, a pulse rate of 76 and a blood pressure of 120 systolic, 80 diastolic. Laboratory examination August 18 was as follows: Undulant fever agglutination was 4 plus in all dilutions to 1:400. The intracutaneous tuberculin test gave negative results. The Kahn reaction was negative. A definitely positive cutaneous reaction with *Brucella abortus* and *Brucella melitensis* persisted for two weeks.

The patient took sulfanilamide 20 grains the first day, 80 grains a day for three days and then from 20 to 40 grains a day for two weeks beginning August 20. At the end of this time he discontinued treatment and stated that he could not distinguish any change in his subjective symptoms. September 16 he was again found to have a 4 plus undulant fever agglutination and was advised to try the vaccine treatment, which was instituted at this time and has been continued to date, with marked improvement of all symptoms.

CASE 6—A man aged 21 who consulted Dr T. L. Wainwright of Oklahoma City July 24, 1938, complained of marked weakness, malaise, generalized aching and dyspepsia. The patient gave a history of having taken over 1,000 grains (65 Gm) of sulfanilamide in daily doses of 60 grains from June 24 to July 10, 1938, for the treatment of gonorrhea.

The patient was given a thorough examination by Dr Minard F. Jacobs, also of Oklahoma City, and Dr Wainwright. He was well developed. The temperature was 100.2 F, the blood pressure 106 systolic, 72 diastolic, and the pulse rate was 120. There were no other physical abnormalities save for tenderness throughout the abdomen, especially in the midepigastrium. He was found to have a markedly increased phagocytosis for *Brucella melitensis* as shown by the opsonic index, a 4 plus undulant fever agglutination and a negative Kahn reaction.

The patient was placed on daily injections of undulant fever vaccines and has made marked and consistent improvement in all symptoms.

#### SUMMARY

Two cases of acute, one of subacute and three of chronic undulant fever—five from my personal practice and one from that of Dr T. L. Wainwright—have been treated by maximum therapeutic doses of sulfanilamide as recommended in the American and British literature of the past year. I have been unable to duplicate the satisfactory results heretofore reported in this condition by the use of this therapeutic agent.

1. Wainwright, T. L. Personal communication to the author.

## DERMATITIS DUE TO BUTYN

HOWARD J PARKHURST M D AND JOHN A LUKENS M D  
TOLEDO OHIO

According to Lundy<sup>1</sup> 'Good surface anesthetics are not common. One that is used with considerable satisfaction is butyn. It is used as a surface anesthetic in 2 per cent solution. It is used for anesthetizing the throat and nose by spraying a small amount of 5 or 10 per cent solution being used. In a 5 or 10 per cent solution as a spray, butyn takes the place of a 10 to 20 per cent cocaine spray for anesthetizing the throat and larynx prior to the introduction of the intratracheal tube under general anesthesia. Butyn is also used with considerable satisfaction by ophthalmologists in an ophthalmic ointment of 2 per cent concentration.

In the use of butyn one should be on guard for idiosyncrasy, since occasions have developed when it seemed that the patient was hypersensitive to butyn. The butyn solution is somewhat irritating when instilled into the eye, and for that reason it has not become as popular as it would have otherwise. It may be used in gels and ointments, in 0.5 or 1 per cent concentration. Butyn is not habit forming.

Since Lundy mentioned the possibility of idiosyncrasy, we had expected that numerous cases of dermatitis due to butyn would have been reported. However, in a careful search through the literature, only three such cases could be found.

In 1924 Greenwood and Quest<sup>2</sup> of Boston reported a case of dermatitis due to butyn, beginning on the hands and arms and becoming generalized. The patient was a urologist who used a 2 per cent solution of butyn with epinephrine as a local anesthetic for passing sounds, for cystoscopic study and for minor operations. Cutaneous tests with this solution were strongly positive (and tests with a 1 per cent solution of procaine hydrochloride were also [less markedly] positive).

In 1927 Lemone<sup>3</sup> of Kansas City, Mo., and Newton<sup>4</sup> of Dallas, Texas each reported a case of conjunctivitis and dermatitis due to butyn. Both patients were women (aged 50 and 66). Lemone's patient, aged 50, had used a solution containing 1 per cent butyn and 0.25 per cent zinc sulfate in her eyes with no apparent ill effects. Seven months later she used the same solution again, and severe conjunctivitis and dermatitis of the lids immediately followed. An intradermal test with 1 per cent solution of butyn was strongly positive, and the conjunctivitis and dermatitis recurred later when this solution was instilled in the eyes. For the local treatment of bilateral glaucoma simplex, Newton prescribed a solution of pilocarpine containing 1 gram (0.06 Gm.) each of butyn and ethylmorphine hydrochloride to the ounce, for home use. A marked dermatitis of the eyelids ensued faded when the butyn was discontinued and recurred within thirty minutes after 4 per cent butyn was used as an anesthetic for taking the tonometric reading.

## REPORT OF CASE

Sept. 7, 1938 one of us (J. A. L.) saw Mrs. O. C. T., aged 49, with a sty of the right upper eyelid and an infected chalazion of the right lower lid. A 2 per cent solution of butyn was instilled in the eye for local anesthesia, and after three instillations the usual chalazion clamp was applied to the lower lid and the infected chalazion was incised. Pus was expressed and granulation tissue curetted away, and the cavity was then wiped out with a cotton tipped applicator saturated with a 1:1,000 solution of merthiolate. The clamp was then removed and the eye bathed with hot compresses to control bleeding and swelling. The patient was instructed to continue the hot compresses at home and to use drops of 0.2 per cent solution of zinc sulfate in 2 per cent boric acid three times a day. September 8 both right eyelids were markedly swollen and itched severely. The drops and compresses were continued and paste of zinc oxide (without salicylic acid) was prescribed for local application.

September 9 there was a more severe dermatitis of the lids, with vesiculation and edema; the eye was swollen shut. An

erythematous vesicular streak, about 5 mm wide, extended down the cheek to the chin, apparently following the path along which a solution had run down. The patient was advised to wash the area night and morning with mild soap and water and to apply moist compresses of a saturated boric acid solution constantly during the day and at night a little plain zinc oxide ointment, rubbed in gently and wiped off with cotton, followed by the application of a little plain talcum. The dermatitis subsided almost completely in a week. In the meantime patch tests with the solution of butyn and with the zinc sulfate solution were applied to the patient's left arm September 10 and removed twenty-four hours later. The reaction to the butyn was positive and increased in intensity, so that three days later the patch was red, vesicular and edematous and the arm swollen and painful. Calamine lotion was ordered, and at the end of a week this reaction had subsided.

This patient showed an intense hypersensitivity to butyn as used in ophthalmologic practice. Perhaps such instances occur more frequently than the paucity of reports would seem to indicate.

## CONFERENCES ON THERAPY

## TREATMENT OF EDEMA

NOTE—These are actual reports, slightly edited, of conferences by the members of the Departments of Pharmacology and of Medicine of Cornell University Medical College and the New York Hospital. The questions and discussions involve participation by members of the college staff, students and visitors.

DR. EUGENE F. DU BOIS: It was only ten or fifteen years ago that there were large numbers of patients in medical wards with extreme grades of edema. They presented a distressing picture. Treatment was most unsatisfactory. Nowadays such patients are relatively few, thanks to the various studies in physiology, biology, chemistry, pharmacology and clinical medicine. Dr. Milhorat will begin the discussion.

## Normal Values

Water content of human body	from 58 to 66 per cent of the body weight
Blood volume of human body	from 79 to 99 cc. per kilogram of body weight
Volume of lymph	from 1,500 to 2,400 cc.
Osmotic pressure of blood serum	30 mm. of mercury
Total serum protein	from 6.5 to 8.2 per cent
Total serum albumin	from 4.6 to 6.7 per cent
Total serum globulin	from 1.2 to 2.3 per cent
Osmotic pressure of serum albumin	is four times that of serum globulin
Hydrostatic pressure	
Arteries	120 mm. of mercury
Capillaries	from 20 to 26 mm. of mercury
Veins	6-7 mm. of mercury
Sacrating in normal adult male	
At rest	from 23 to 30 C. skin and lungs
From 29 to 33 Gm	per kilogram
At rest	from 30 to 35 C. skin and lungs
From 100 to 120 Gm	per hour
Vigorous muscular exercise	up to 230 Gm. in 12 minutes
800 Gm	in 35 minutes

DR. A. T. MILHORAT: Edema is a symptom and sign, not a disease. Various and diverse are the factors which can bring it about. Some of these factors are still obscure but many of them are now fairly well known, such as the role of blood proteins, of the  $pH$  of the tissues and of potassium and sodium ions, and the effect of salt on the osmotic pressure of proteins. Through analysis of these and others we are able to comprehend better the treatment of edema and the successful results as well as the failures.

1 Lundy, John S. The Use of Local Anesthetics. J. A. M. A. 107: 1468 (Oct. 31) 1936.

2 Greenwood, Arthur M. and Quest, James F. A Case of Butyn Dermatitis. J. A. M. A. 83: 1077 (Oct. 4) 1924.

3 Lemone, Albert A. Conjunctivitis and Dermatitis Due to Butyn. Am. J. Ophth. 10: 125 (Feb.) 1927.

4 Newton, F. H. Conjunctivitis and Dermatitis Due to Butyn. Am. J. Ophth. 10: 412 (June) 1927.

Some of the mechanisms that cause edema are

- 1 Increased permeability of the capillary wall (snake venom, asphyxia)
- 2 Decrease in the osmotic pressure of the blood, as after plasmapheresis and repeated hemorrhage and in cases of massive albuminuria. The thinner fluid, one might say, is drawn into the tissues
- 3 Increased hydrostatic pressure in the vessels of the region involved (cardiac failure, varicose veins). In this case it might be said that the fluid is forced into the tissues
- 4 Retention of certain substances the accumulation of which disturbs the normal osmotic relationships between the blood plasma and the tissues. Edema arising as the result of the use of sodium chloride in patients with impaired capacity for its excretion is an illustration of this fact

There are several clinical varieties of edema—cardiac, renal, nutritional, toxic, obstructive. Each presents its own peculiar problems in treatment. The factors which require consideration in every case of edema are (1) diet (protein content, acid or alkaline ash), (2) fluid intake, (3) salt intake, (4) diuretic agent and (5) special measures directed to the underlying disease itself.

In most cases of heart failure digitalis suffices to abolish edema indirectly by improvement of the circulation through the kidney. There are many cases, however, in which that is not enough and in these some of the diuretics alone or in combination often produce dramatic results. The more important diuretics are (1) the purine bases, or xanthines, (2) the organic mercurials, (3) the acid-forming diuretics and (4) nonthreshold diuretics.

The purine bases or the members of the caffeine group have long been used as diuretic agents but are perhaps not so popular today as some of the others. The use of caffeine itself is limited by the fact that it tends to cause restlessness and insomnia. In theobromine and theophylline the diuretic action is stronger and they exert relatively less stimulant effect on the higher centers. These compounds are insoluble in water but go into solution readily when mixed with such salts as sodium acetate, sodium salicylate or calcium salicylate. The insoluble theophylline (theocine) may be used as such in oral doses varying from 1½ to 9 grains (0.1 to 0.6 Gm.) three times daily. It tends to irritate the gastrointestinal tract and vomiting is caused in some individuals by even small doses. The soluble double salts (theobromine with sodium salicylate, theophylline with sodium acetate or theobromine with calcium salicylate) are said to be less irritant but the evidence is not conclusive. Only about 50 per cent of their weight is the purine base. The double salt of theophylline is given in doses of about 3 to 15 grains (0.2 to 1 Gm.) three times daily, those of theobromine in doses of from 15 to 30 grains (1 to 2 Gm.) in a similar way. Theophylline with ethylene diamine (aminophylline) is also effective in comparable amounts; it contains somewhat more of the base, namely about 75 per cent of its weight. How the purines act to produce diuresis is not fully established. Various views have been advanced—increased renal blood flow, some extra-renal action, or direct action on the renal epithelium. Increase in glomerular filtration appears to be the outstanding phenomenon.

The most effective diuretics in use at the present time are the organic mercurials. There are several such preparations. The older merbaphen (novasurol) has now been virtually replaced in practice by mersalyl (salyrgan). Other similar preparations are neptal and

mercaptopurin. All of these exert essentially similar actions. They are supplied on the market in ampules in which 1 cc. of the solution represents approximately 40 mg. of mercury in nonionizable form. There is available a rectal suppository known as mercurin and another of salyrgan. These contain much larger amounts of mercury and sometimes cause rectal irritation. They are useful, however, in cases in which the frequent injection of a drug is not feasible. The dose of the solutions of these mercurials in the treatment of cardiac edema is from 1 to 2 cc. by intravenous injection. They are sometimes given intramuscularly but are liable to cause pain at the site of injection. Great care must be taken to avoid leakage into the subcutaneous tissues, for this will cause local necrosis and slough. The use of a very small needle for the intravenous injection helps to prevent this. The interval between doses varies greatly, depending on the severity of the edema. Usually an injection every second or third day suffices, sometimes a daily injection is necessary, often an injection once a week will prove sufficiently effective. As a rule, the necessary dosage for maintaining a patient free from edema causes no appreciable injury to the kidney, although occasionally patients unduly sensitive to the action of mercury are encountered, and these may show signs of mercury poisoning—renal damage, stomatitis, vomiting and bloody diarrhea. It is wise, therefore, to make frequent urine examinations for the presence of blood cells and for increase in albumin or casts during a course of treatment. The mechanism of the diuretic action of the organic mercurials is not established. In contradistinction to the xanthines these are generally believed to act primarily by decreasing tubular reabsorption.

An acid-forming diuretic, such as ammonium chloride, is often administered together with the organic mercurial. As I shall mention presently, increased acidity of the tissues favors diuresis, also a normal blood chloride is necessary for effective diuresis. The majority of cases, however, do quite well with the mercurial alone.

There are several compounds belonging to the group of so-called acid-forming diuretics, such as calcium chloride, ammonium chloride and ammonium nitrate. These substances, when given in large amounts, shift the acid-base equilibrium of the body toward the acid side. In the case of ammonium chloride the chemical reaction involves the conversion of ammonia to urea with the liberation of the acid ion. In the case of calcium chloride the reaction with carbonic acid produces calcium carbonate and hydrochloric acid. The diuretic action is due not solely to the acidity, however, but also to the character of the acid radical, for in some cases ammonium chloride, in other cases ammonium nitrate proves more effective.

Ammonium chloride and ammonium nitrate are among the most useful members of this group. They are used in total amounts of about 6 Gm. daily given in single doses of 2 Gm. three times a day. A convenient form is a tablet coated with phenyl salicylate of 0.5 Gm. each.

Urea is a nonthreshold substance which the kidney excretes as soon as it enters the blood stream and it takes with it quantities of water. It has been used in various types of edema with favorable results for about half a century. It is sometimes useful in patients with nephritic edema in whom the blood urea is not elevated but the most striking effects are seen in patients with

**cardiac edema** Large doses are necessary, namely from 30 to 60 Gm daily given in single doses of from 10 to 20 Gm three times a day. It has a disagreeable metallic taste and sometimes causes vomiting. It is best given after meals, well diluted with water or orange juice. Excessive doses cause weakness and lassitude, associated with very high blood urea values (from 80 to 90 mg per hundred cubic centimeters).

The diuretic effect of the purine bases, the organic mercurials and urea begins within a few hours after the dose, and the effect of any given dose is usually over within approximately twenty-four hours.

The accumulation of sodium in the tissues tends to promote the accumulation of water. The administration of potassium salts, however, tends to increase the excretion of sodium. Potassium salts therefore, are occasionally very effective as diuretics. Potassium nitrate is the compound generally employed, in doses of about 5 Gm daily. It sometimes produces a marked diuresis in patients in whom other agents have proved unsuccessful. The potassium ion is more toxic than sodium and in the presence of severe renal injury potassium salts must be given with caution, since the kidney may fail to eliminate them adequately, in which case the potassium concentration of the blood may rise to toxic levels.

The restriction of salt intake in patients with edema is usually desirable. When the ability to excrete salt is impaired the use of salt sometimes causes a rapid increase in the edema and, conversely, the restriction of salt may be followed by a decrease in the edema.

The restriction of water involves several considerations. It is usually advisable to restrict the fluid intake to about a liter a day. However, excessive restriction of water may prove injurious. Newburgh showed that patients with impaired ability to concentrate the urine will often show a decrease in edema when the fluid intake is increased. He believes that enough water should be given so that the specific gravity of the urine is kept below the maximal specific gravity of which the kidneys are capable. Normally the kidneys require around 600 to 700 cc of water daily to excrete the waste products. Patients with an impaired ability to concentrate the urine require larger amounts of water. For such patients restriction of fluids will increase the edema, where the administration of adequate amounts of water will decrease it.

#### TREATMENT OF NEPHROSIS AND NEPHRITIS

DR LEE C. FARR (of the Rockefeller Institute) In the treatment of edema a disease which is called pure lipid nephrosis has occupied an important experimental role because in this disease we have a process in which edema is formed in the individual without renal failure and without cardiac failure, in other words, probably here the physical-chemical mechanism for the exchange of fluid between the vascular system and the tissues is the one primarily at fault in the edema formation.

In the normal blood serum or plasma the proteins exert an osmotic pressure of approximately 30 mm of mercury. The osmotic pressure might be simply defined as the attraction of the solute for the solvent, in other words a plasma protein concentration of from 6.5 to 8.2 per cent, with an albumin above 4, will attract water to such an extent that 30 mm of mercury pressure is exerted in an osmometer.

As the blood enters the capillaries the hydrostatic pressure due to the blood pressure is greater than the osmotic pressure. This difference in pressure varies with the point at which the measurements are made because there is a fall in the hydrostatic pressure as the blood progresses through the capillary system, but at approximately the arterial end of the capillaries the total hydrostatic pressure would be about 45 mm of mercury.

Since the osmotic pressure of serum is approximately 30 mm of mercury, that would give a pressure gradient of about 15 mm of mercury. In other words, water tends to diffuse out of the vascular bed and into the extracellular spaces. On the other hand, farther along the capillary the hydrostatic pressure falls, so that at some point there is equilibrium, and at this point there will be equal diffusion from within the capillary out and from the extracellular spaces into the capillary. At the venous end of the capillary, with a further drop in the hydrostatic pressure, we find a negative gradient of about 20 mm, which tends to enhance the transfer of water from the extracellular spaces in the capillary bed. Under normal conditions these processes of diffusion out and in are balanced so that the full quantities of water which are extruded from the vascular bed are resorbed in the capillaries and the lymphatics. In nephrosis, which exemplifies the effects of a reduction of the serum protein, instead of there being an osmotic pressure exerted of 30 mm there is a pressure of something less than 30 mm, depending on the reduction in protein.

With a reduction in serum osmotic pressure, a glance

at the illustration will make apparent that throughout most of the course of the capillary the hydrostatic pressure is exceeding the osmotic pressure, so that diffusion of fluid from the vascular system to the extracellular spaces is enhanced, while in only a relatively short distance and at a diminished pressure gradient is fluid transferred from the extracellular spaces back into the capillary. A rise of venous pressure would exert essentially the same effect. It is purely the relationship between the hydrostatic pressure which is existing in the system at any point, tending to push the fluid out, and the osmotic pressure, which tends to withdraw fluid from the extracellular spaces.

It would seem, of course, that the ideal way to treat this condition is to increase the osmotic pressure of the blood serum or plasma. This can be done in a variety of ways. Of course it can be done by increasing the plasma protein. Such an increase occurring spontaneously may be seen in patients with nutritional edema. With adequate nutrition being provided, the plasma proteins rise to their normal level and edema disappears. The osmotic pressure may be increased by the intravenous administration of acacia, which, being a nondiffusible substance, raises the colloid osmotic

Schematic representation of fall in hydrostatic pressure in a capillary and its relation to the colloid osmotic pressure of plasma shown here as 30 mm of mercury. The arrows represent the resultant diffusion effected as a difference in the two pressures. A hydrostatic pressure B capillary wall C osmotic pressure

pressure of the blood in proportion to its plasma concentration. It has been attempted by the administration of concentrated human serum and also by the administration of blood by transfusion.

In the treatment of nephrosis, however, none of these methods are particularly satisfactory. Acacia is a foreign substance, which tends to accumulate in the liver, and the ultimate effects of acacia are not entirely understood, in addition to which following the administration of acacia severe reactions may be encountered in patients, which may be of such a degree as to induce an acute uremia.

The administration of plasma protein by transfusion or concentrated serum is not satisfactory because in nephrotic individuals the extra plasma protein which is administered intravenously is lost usually within twenty-four to forty-eight hours in the urine. As a result, benefits obtained by such treatment are usually transitory, although occasionally a patient does seem to be permanently benefited.

In adults, when the plasma albumin is reduced below approximately 2.5 Gm per hundred cubic centimeters of plasma, salt restriction and administration of diuretics such as urea are usually ineffective in controlling the edema. Thus, then, we take as the critical level for edema formation in adults. In children, however, the critical level is approximately 1.2 Gm per hundred cubic centimeters of plasma. These figures are for the plasma albumin. The osmotic pressure of globulin is relatively insignificant in comparison with the albumin. Why this difference should exist between adults and children is not clear, because osmotic pressure measurements on these serums are in essential agreement with the albumin content. These are merely empirical figures which have been observed in the clinic. When a child's plasma albumin—a child around 4 or 5 years—is below 1.2, diuretic measures are not of much avail, and, when the adult's plasma albumin is below 2.5, again diuretic measures are not of much avail. However in a nephrotic child with the plasma albumin above 1.2 Gm per hundred cubic centimeters very often striking and remarkable results are obtained by the administration of almost any diuretic or usually simply by salt restriction.

In the attempt to build up plasma protein in these patients it has been customary to feed a high protein diet. A high protein diet has several effects. In the first place, it increases the quantity of urea which is available for excretion and thereby acts much the same as the simple administration of urea. This effect is primarily diuretic. A second effect of high protein feedings, which in children with pure lipoid nephrosis and in dogs is relatively easy to demonstrate, is what we may interpret as an increased renal blood flow reflected by an increase in the urea clearance.

With an increased renal blood flow one might expect an increase in the glomerular filtrate with a corresponding increase of water elimination. The exact mechanism is not yet worked out, but with an increase of renal blood flow and urea excretion usually more salt and water are eliminated and the effect is very roughly proportional to the quantity of protein that is fed in the diet.

The third effect, which is really what we are seeking, is to provide nitrogen for restoration of tissue proteins and plasma proteins. To promote optimal nitrogen assimilation there are certain restrictions that must be

introduced in the use of a high protein diet. Nephrotic children fed 0.5 Gm of protein per kilogram of ideal body weight can be shown to be on a negative nitrogen balance. Obviously we cannot hope for restoration of plasma protein with the patient on a negative nitrogen balance, as a matter of fact, a decrease in plasma proteins might be expected if the diet is fed for a long enough period of time. With an increase of protein in the diet, from 0.5 to 1, 2 and 3 Gm per kilogram of ideal body weight, the children show an increasingly positive nitrogen balance and accordingly are, I believe, under conditions which tend to promote the restoration of tissue and plasma protein.

However, when the protein in the diet is increased above 3 Gm per kilogram of ideal body weight, not only is there no further increase in positive nitrogen balance but actually there is a decrease in the nitrogen assimilated, so that a child may be on a negative nitrogen balance with a protein intake of 5 Gm per kilogram of ideal body weight, whereas he is on a positive nitrogen balance at 3. The point at which this break in nitrogen assimilation occurs is quite sharp and is apparently at about 3 Gm per kilogram of ideal body weight. Apparently, in children with increasing protein intakes there is a speeding up of the catabolic processes, and on a very high protein diet the nephrotic child may actually be on a negative nitrogen balance. This fact may be deceptive clinically, because with this very high protein diet the initial increase in excreted urea due to dietary protein and destroyed tissue may cause a temporary diuresis with apparent clinical improvement. Such a paradox will occur only when the plasma albumin is above the critical edema level.

In the adult we give about 1.5 Gm of protein per kilogram of ideal body weight. It is obvious that the patient cannot be fed on his actual body weight, because he may weigh as much as 50 per cent over his expected weight. A diet calculated on his ideal body weight provides an adequate amount of nitrogen for the restoration of protein tissue with a sufficient excess provided for wear and tear quota. The actual protein fed per kilogram of protein tissue in these patients is quite high because of the severe malnutrition due to nephrosis.

The general caloric intake, of course, must be kept adequate throughout any protein-feeding period. In general, if one is desirous of controlling the edema in nephrotic patients it is best to place them on as ideal a protein intake as possible in order to promote the regeneration of tissue and plasma proteins and then if necessary to supplement this by the judicious use of diuretics. The diuretic would not be indicated until the plasma albumin exceeds the critical edema level. The permanence of any improvement will depend ultimately on the restoration of tissue and plasma proteins to a normal level and it is well to be cautious in the use of diuretics on these patients so that the physician does not delude himself into believing that the unphysiologic state attained as a result of the use of diuretics represents material improvement of the patient.

#### DISCUSSION

STUDENT Does this 3 Gm of protein per kilogram of body weight apply to both the child and the adult or only to the child?

DR FARR That is only in the child. In the adult we give about 1.5 Gm per kilogram of ideal body weight because no provision is necessary for growth require-

ments in the adult. The tendency of children to go into a negative balance on a high protein intake is what we call paradoxical dumping. It occurs in normal children as well as in nephrotic children. The mechanism is not well understood. Apparently in the normal child the level at which the paradoxical dumping occurs is somewhat higher than in the nephrotic children. Probably in the normal child it is around 4 Gm per kilogram of ideal body weight.

**STUDENT** For the patient who has a retention of urea wouldn't ammonium chloride be contraindicated on the basis of its forming further urea to be excreted?

**DR MILHORAT** I think not. The ammonium chloride is given in small amounts, whereas the amount of urea normally excreted is from 20 to 30 Gm daily. If you estimate the amount of urea formed from the ammonium chloride which is administered, it will be found to be small. I should like to know whether Dr Farr has noticed any difference in the effectiveness of the different proteins. One would expect a difference between a protein like fibrin, which is complete, and one like gelatin, which is very unsatisfactory as a nutritive substance.

**DR FARR** It is almost impossible to give pure proteins in the diet. You cannot feed patients just gelatin or casein and get them to take it. Experimentally, apparently lactalbumin, casein and beef protein have about the same quality with regard to regeneration of plasma protein. Ox serum protein seems to surpass each of the others. That seems to be about the best protein that could be used if one is restricted to feeding a single protein, but the difference between ox serum protein and a well rounded diet with about 70 per cent of the protein in the diet as animal protein is not sufficient to warrant an attempt to feed a patient on pure ox serum protein. Experimentally in dogs there is an advantage, a theoretical advantage, but practically in the treatment of patients it is not sufficient to warrant the use of a purified protein product. Further, in these individuals we have done amino acid studies and, as far as we can tell from a study of the blood and the amino acid curve after the ingestion of protein, proteins are broken down and absorbed in a normal fashion in these patients. There apparently is no inability, as far as the patient is concerned, to digest and absorb the amino acids of which the proteins are constituted. Knowing that, one would hardly expect much difference between the different proteins as they occur in nature. In the treatment of this particular complex, no one has demonstrated a specific amino acid deficiency, although there has been some evidence that probably cystine might be a little bit lacking in these patients.

**DR EPHRAIM SHORR** Dr Farr, in the frequently occurring spontaneous improvements in children—that is, when they are not placed on any specific type of diet—do you notice corresponding changes in the plasma protein?

**DR FARR** You mean a child is going along without any change in his regimen and suddenly develops a diuresis and apparently is cured?

**DR SHORR** Yes.

**DR FARR** Not necessarily. I have seen diureses occur in these children with a shift in the plasma albumin from 11 to 13, which is certainly in ordinary parlance not significant, but it is amazing how sharply

this critical level is observed by the children, and a very slight deviation on either side will lead to the production of edema or the loss of edema.

**DR SHORR** I wondered whether we might not at the same time think of other factors. One thing that we note clinically is that edema is uncommonly associated with uremia. Wouldn't that possibly point to some influence of the diminished plasma protein on renal excretion itself? That is, may we not consider the renal filtration as taking place under the same circumstances as occurs in filtration of water in the peripheral tissues? So that if you diminish your plasma proteins as you find them diminished, I will say, in nephrosis, you then have a blood with a lowered plasma protein passing through the glomerulus. The decreased osmotic pressure of the proteins is going to offer less resistance to filtration. From the standpoint of the kidney this would seem a very desirable circumstance. This should increase the glomerular filtration and in that way increase the actual renal secretion of urea and all the other metabolites that go with it. It may be that it is that factor rather than a slight shift in the level of the proteins which may bring about the sudden diuresis, when children with nephrosis spontaneously lose their edema.

**DR FARR** That is an interesting possibility. In these children the urea clearance will run anywhere from 140 to 300 per cent normal, which indicates an increased renal blood flow. Presumably as the blood goes through the capillary there is an increased capillary filtration due to the reduction in osmotic pressure, but surprisingly enough there also seems to be an increased tubular resorption of water, which more than offsets the increased glomerular filtration, so that the concentration index or the U over B ratio, instead of running around 50 as seen in normal individuals, may go up as high as 100 in these children, which would indicate an excessive concentration of urea in the kidney tubules.

**DR SHORR** So that waste products will be eliminated favorably under these conditions with not necessarily a concomitant elimination of water?

**DR FARR** Water and salt are reabsorbed to an exceedingly great extent.

**DR SHORR** If this increased glomerular filtration as a result of low plasma protein is a factor in human disease, it might be a possible explanation for the observation that patients with edema do not go into the state of nitrogen retention quite as readily as the other type of nephritic?

**DR FARR** What we find is that we can divide these edematous patients into two groups: those with no impairment of nitrogen excreting abilities, and usually their urine nonprotein specific gravity is also normal; and those with an impairment of nitrogen excreting abilities and a reduction in the urea clearance with or without evidence of any nitrogen retention. The reduction of plasma protein does not seem to be the determining factor in inhibiting or enhancing nitrogen retention. In following those patients along a rapid rise in the serum proteins from a pathologic level with the albumin at about 1 per cent to a normal level with the albumin at about 4 per cent occurring in a period of three weeks is not accompanied by any demonstrable change in renal function. In acute uremia particularly that which is terminal there is such a reduction in the number of functioning glomeruli that it is mechanically impossible

for the body to lose protein as rapidly as it is formed apparently, and the reabsorptive mechanism of the kidney is so seriously impaired that it cannot concentrate the glomerular filtrate to the same extent as it does before that particular phase has been reached. So that in uremia paradoxically enough you often see an improvement in edema accompanied by a loss of electrolytes, and in uremia it is necessary often to give these patients sodium chloride in order to preserve their electrolyte balance. I have seen one girl whose plasma chloride went down to 40 milliequivalents in a terminal uremia, which is less than half the expected normal.

DR DU BOIS: Dr Farr, I think a good many of us have noticed that fairly frequently patients given diuretics get a good diuresis and that their general condition becomes much worse following the use of the diuretics. Would you explain that on the same basis?

DR FARR: Well, it is possible to explain it on the same basis. On the other hand, these patients can show what amounts to a vascular dehydration in the face of edema. That is, apparently they will, even with edema present, show the same response to the lack of fluid as a normal individual. Now apparently in some instances when given diuretics this condition prevails and they have an apparent vascular dehydration with also a loss of extracellular water, which induces an apparent—well I should almost have to call it shock, it is not shock, but that comes the closest to describing it—and by the restoration of fluid volume these patients will often make a spectacular improvement with only a slight increase in their weight and without recovering all the edema that was lost during the diuresis.

DR DU BOIS: I think the group would appreciate it if you would review some of the contraindications for the use of diuretics. That is a tremendously important clinical question.

DR FARR: In the treatment of nephritis, one must always be on the lookout for the development of acidosis, and with the development of acidosis of course the acidifying diuretics are definitely contraindicated. In the use of an acidifying diuretic, ammonium chloride, in a nephritic patient, it is desirable, in fact it is almost necessary, to follow the carbon dioxide or chloride to prevent the development of an excessive acidosis with a concomitant uremia. These patients sometimes, even on a small dose of ammonium chloride, will go into uremia in a couple of days, and it is impossible to make a prognostication before the dose has actually been tried as to whether any patient will develop an acidotic uremia under these circumstances or not. If these patients do develop a severe acidosis, discontinue the drug and treat them with alkalis. Mercurial diuretics, I feel, are contraindicated in renal lesions because almost invariably we have found in the administration of the mercurial diuretic, if the urine is carefully examined, that one can find a shower of red blood cells and casts with or without diuresis.

In individuals who have a normal functioning kidney, as in cardiac cases, we have followed the urea clearance after the administration of mercurial diuretics, and curiously enough despite the induction of a most satisfactory diuresis we have often observed an actual fall in the apparent renal function, very consistent in one individual, not great, but always about 10 per cent from the preexisting level, returning to normal within twenty-four to thirty-six hours after the administration

of salyrgan or mercurpurin. We feel that since the primary action of these mercurial diuretics is probably on the tubules, and since in the nephrotic syndrome it is the tubule that is most seriously involved, any diuretic which would act on the tubule would be contraindicated.

Our choice of a diuretic in cases of nephritis and nephrosis is urea, and the dose will vary somewhat with the individual. In general we give as much as 40 or 45 Gm a day even to a 5 year old child, where the urea-excreting mechanism is normal. Where you have impairment of renal function, the dosage of urea should be determined by the elevation of the blood urea nitrogen and an increase of more than 10 to 15 mg per hundred cubic centimeters should mean a reduction in the dose. The mere elevation of the blood urea nitrogen does not seem to be harmful. I have seen it rise from a value of 16 mg per hundred cubic centimeters to 82 mg in a patient by feeding urea without any apparent deleterious effects—no change in the renal function—but we are always a bit hesitant to continue the drug under these circumstances, and certainly the piling up of urea in the blood is to be avoided. When urea increases in the blood to 10 or 15 mg higher than it was at the beginning of treatment, the maximal diuretic effect that can be obtained with urea is usually present.

DR HENRY B. RICHARDSON: There was mention of potassium salt. There was some old work tending to show that potassium had an adverse effect on the kidney, wasn't there? It was an old article of Smillie's on that point.

DR FARR: Potassium and magnesium still are not clear as to their effect on the kidney, whether they are actually deleterious or not, but certainly in these patients where you have—and you always have—an impairment of excretion of these materials, one must be quite circumspect about using potassium or magnesium salts as a diuretic.

DR HARRY GOLD: Did you ever use thyroid?

DR FARR: Yes, without any consistent effect.

DR MILHORAT: May I ask Dr Farr whether he feels that it is a rational process ever to give amino acids intravenously in any of these cases?

DR FARR: Amino acids have not been tried in this condition because they have not been available. A preparation that was suitable for intravenous use has certain theoretical advantages and a good many practical disadvantages, but theoretically it would seem to be ideal to feed these patients that way when they are unable to take anything by mouth, thus supplementing their diet. We plan to try this.

DR MILHORAT: May I say a word about the administration of the amino acids? If the technique should be perfected, I think it will be found that the proportions or the relative amounts of the amino acids will be as important as the kinds of amino acid used. In my own work I found that the concomitant administration of a complete protein had no effect on the ability of the animal to utilize gelatin. Blood fibrin is a complete protein, and all the nitrogen is retained by the fasting dog. On the other hand, most of the nitrogen of gelatin, which is an incomplete protein, is excreted. The amino acids in blood fibrin are in such amounts that there are not enough of the nondispensable ones left to make gelatin a complete protein.

## Council on Pharmacy and Chemistry

### NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

PAUL NICHOLAS LEECH Secretary

### ANTIPNEUMOCOCCIC SERUM, TYPES I AND II COMBINED (See New and Nonofficial Remedies, 1938, p 399)

The Gilliland Laboratories Inc., Marietta, Pa

*Antipneumococcic Serum Refined and Concentrated Types I and II*—Prepared by immunizing horses with intravenous injections of the virulent and avirulent cultures of type I and type II pneumococci. Trial bleedings are made at frequent intervals and when the serum has reached a sufficient degree of potency for type I and type II pneumococci the horses are bled aseptically and the serum is refined and concentrated by the method of Lloyd D Felton (*J Infect Dis* December 1928 p 543). The concentrated product contains type I and type II pneumococcus antibodies. After concentration sterility tests are carried out in the manner prescribed by the National Institute of Health and safety tests are carried out by injection into white mice and guinea pigs. The potency of the product is expressed in terms of the unit described by Felton (*Boston M & S J* May 15 1924 p 819 *J Infect Dis* September 1925 p 199 October 1925 p 309) the unit being  $\frac{1}{100}$  cc for type I and  $\frac{1}{10}$  cc for type II of the control serum (P 11) distributed by the National Institute of Health. Marketed in packages of one syringe containing 10 000 units each of type I and type II and in packages of one syringe containing 20 000 units each of type I and type II pneumococci each accompanied by a vial of dilute serum (1:10) for the sensitivity test.

### AMYTAL (See New and Nonofficial Remedies, 1938, p 111)

The following dosage forms have been accepted

*Elixir Amytal 2 grains per fluidounce* Amytal approximately 0.44 Gm per hundred cubic centimeters in a vehicle containing alcohol 30 per cent glycerin water and aromatics methenamine 2 grains per fluidounce is present for the purpose of increasing the solubility of the amytal.

*Elixir Amytal 4 grains per fluidounce* Amytal approximately 0.88 Gm per hundred cubic centimeters in a vehicle containing alcohol 34 per cent glycerin water and aromatics methenamine 4 grains per fluidounce is present for the purpose of increasing the solubility of the amytal.

## Council on Foods

### ACCEPTED FOODS

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COUNCIL ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION AND WILL BE LISTED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED

FRANKLIN C BING Secretary

### LIBBY'S HOMOGENIZED BABY FOODS FORMULATED COMBINATIONS

NOS 1, 2, 3, 4, 5 AND 6

*Manufacturer*—Libby, McNeill & Libby, Chicago

*Description*—Canned preparations of homogenized vegetable fruit cereal and soup mixtures, intended for infant feeding or as foods in special diets, available in the following combinations

1 Peas, beets and asparagus in equal quantities, with small amounts of added water and salt

2 Pumpkin, stringless beans and tomatoes (skin and seeds removed) in equal quantities, with small amounts of added water and salt

3 Carrots, spinach and peas in equal quantities with small amounts of added water and salt

4 Whole milk whole wheat flour and soya flour, with a small amount of salt

5 Strained stewed prunes, with small amounts of lemon juice and pineapple juice

6 Tomato juice, celery carrots chicken livers barley flour and water, slightly seasoned with onion and salt

*Manufacture*—The specified ingredients for each combination are mixed in formula proportions heated and a small amount of water added if necessary to furnish the desired consistency. The mixture is then strained in an atmosphere of steam through

a stainless steel screen, and the strained mixture is further subdivided or homogenized by being forced through stainless steel valves under 3 500 to 4 500 pounds pressure, after which they are packed in enamel-lined containers and heat processed.

*Analyses* (submitted by manufacturer) —

Calories per ounce	9.7	4.0	9.4	26.4	36.6	9.4

*Vitamins*—The firm has provided protocols of biologic assays which show the various combinations to have the following vitamin content

*Vitamin A* U S P units Per gram—(combination 1) 3.3, (2) 20 (3) 30 (4) 18, (5) 7.1, (6) 57 per ounce—(combination 1) 94 (2) 554 (3) 850 (4) 52, (5) 200 (6) 1 630

*Vitamin B<sub>1</sub>* international units Per gram—(combination 1) 0.19 (2) 0.14 (3) 0.19 (4) not reported (5) 0.16 (6) 0.26, per ounce—(combination 1) 5.5, (2) 4.2, (3) 5.5 (4) not reported, (5) 4.8 (6) 7.5

*Vitamin C (ascorbic acid)* milligrams Per gram—(combination 1) 0.084 (2) 0.056 (3) 0.081 (4) 0.014 (5) 0.106 (6) 0.038, per ounce—(combination 1) 2.40, (2) 1.60, (3) 2.31 (4) 0.40, (5) 3.02 (6) 1.1 International units Per gram—(combination 1) 1.68 (2) 1.12 (3) 1.63 (4) 0.28 (5) 2.12 (6) 0.76, per ounce—(combination 1) 47.71, (2) 31.81, (3) 46.29, (4) 8, (5) 60.21, (6) 22

*Vitamin G (riboflavin)* Bourquin-Sherman units Per gram—(combination 1) 0.281 (2) 0.147, (3) 0.264 (4) not reported, (5) 0.352 (6) 0.528 per ounce—(combination 1) 8.0 (2) 4.2, (3) 7.5 (4) not reported, (5) 10.0 (6) 15.0

*Claims Recognized by the Council* There is evidence that fruits and vegetables in finely divided form such as these homogenized foods are well tolerated by infants as young as 1 or 2 months of age. Because the amounts of iron and vitamin B<sub>1</sub> of the diet of the infant may require more attention than has been given them in the past some pediatricians may consider that even small amounts of foods containing these nutritional essentials may be a desirable addition to the diet of the young infant. Libby's Homogenized Baby Foods are accepted as foods suitable for use particularly during the early months of infancy.

### CLAPPS CHOPPED PRUNES

*Manufacturer*—Harold H Clapp Incorporated, Rochester, N Y

*Description*—Canned chopped prunes, flavored with lemon juice

*Manufacture*—Prunes are pitted washed and chopped. Lemon juice is added. The mixture is heated in an atmosphere of steam, adjusted to standard consistency, filled into cans, sealed, processed under pressure in steam retorts and cooled.

*Analysis* (submitted by manufacturer) — Moisture 70.0%, total solids 30.0%, ash 0.7%, fat (ether extract) 1.5%, protein (N x 6.25) 1.1%, crude fiber 2.4%, carbohydrates other than crude fiber (by difference) 24.3%

*Calories*—12 per gram 34 per ounce

## IODINE BALANCE IN EXOPHTHALMIC GOITER

The discovery by Baumann in 1895 that the thyroid gland of mammals contains iodine in organic combination stimulated other investigators in their attempts to throw light on the true nature of diseases of the thyroid. Two decades after Baumann's observation, Kendall succeeded in isolating the iodine-containing amino acid thyroxine, the active principle of the gland. Elaborate statistical studies point to the interrelationship of the prevalence of goiter in certain localities and the amount of iodine available to inhabitants of these districts. Measures based on this relationship have had widespread influence on public health.

Iodine is an essential component of the thyroid hormone and thus thyroid function and iodine metabolism are intimately related. A recent study of the iodine balance in exophthalmic goiter by Puppel and Curtis<sup>1</sup> is an important contribution to our knowledge of the nature of hyperthyroidism. These investigators realized that the effect of hyperthyroidism on the metabolism of iodine is significant in considerations of disturbed thyroid function. Although hyperiodemia and hyperioduria had been shown in patients with exophthalmic goiter, it remained necessary to study the intake and the excretion of iodine by both normal persons and patients suffering from exophthalmic goiter in order to have a comparative study of iodine metabolism. By carefully controlling the diet, Puppel and Curtis were able to maintain normal subjects on a low intake of iodine. Under these conditions it is found that more iodine is excreted than is taken in, normal persons on a low iodine intake are unable to maintain a positive iodine balance. Persons receiving an average of 29 micrograms of iodine daily lost this element to the extent of 42 micrograms a day. A similar study made on normal subjects during starvation shows that the excretion of iodine in the sweat, feces and urine continues so that an even greater negative balance results. Examination of the iodine excretion

of a pregnant woman on a low intake of iodine revealed the fact that the net loss of iodine continued through the eighth month of gestation. A possible explanation of this negative balance in normal persons on a low intake of iodine is that some of the iodine resulting from the breakdown of thyroid hormone is not then available to the thyroid or other tissues and is consequently excreted. Indeed, other investigations indicate that from 163 to 325 micrograms of iodine is utilized daily in the form of thyroxine.

Patients with exophthalmic goiter, maintained on a low intake of iodine, show a negative iodine balance which is from two to three times that observed for normal persons under similar conditions. Although under these conditions the greatest excretion occurs through the urine, the feces are responsible for 40 per cent of the total elimination whereas normal persons maintained on a low iodine intake excrete only 15 per cent in the feces. On an intake of iodine sufficient to keep a normal subject in positive iodine balance, patients with exophthalmic goiter excrete more iodine than they receive and are thus in a negative iodine balance. Feeding of increased amounts of iodine to a normal person previously on a low intake of iodine produces an immediate positive balance. Similar treatment of a patient with hyperthyroidism results in an immediate pronounced retention of iodine and a consequent positive balance which is twice the normal. Patients with exophthalmic goiter show iodine values in the blood which average 9 micrograms per hundred cubic centimeters, in contrast to the value of 4.3 in normal subjects. These data indicate that the increased amount of blood iodine in hyperthyroidism may result from augmentation of total iodine metabolism. There is an increase in its mobilization and an increase in its excretion through one or all of the excretory channels.

These profound changes in iodine metabolism are abolished by thyroidectomy. One patient showed complete recovery from symptoms characteristic of exophthalmic goiter two years and seven months after adequate subtotal thyroidectomy. At this time the iodine balance was normal, although previous to the operation a negative iodine balance had existed despite an adequate intake of iodine. A patient with toxic nodular goiter and hyperthyroidism showed a dramatic fall in excreted iodine to within normal limits as early as the sixth day after thyroidectomy with concomitant clinical improvement. In another case, in which medical management alone brought about clinical improvement, the excretion of iodine decreased and the balance returned to within normal limits.

Although the research by Puppel and Curtis bears directly on the problem of iodine balance in exophthalmic goiter, it also extends our conception of the function of the thyroid gland and has helped further the integration of the various aspects of the problem of thyroid function.

## EXPERIMENTAL ECLAMPSIA

The recent demonstration by Dill and Erickson<sup>1</sup> of Duke University that a typical eclampsia-like syndrome can be produced in pregnant dogs and rabbits by a simple operation on the kidney suggests a new theory as to the etiology of toxemia of pregnancy and makes possible an intensive laboratory study of the nature and treatment of this disorder. Sheep and guinea pigs occasionally develop eclampsia-like symptoms during gestation. A highly fatal toxemia of pregnancy also occasionally develops in rabbits. Eclampsia in rabbits has been extensively studied by Greene<sup>2</sup> of the Rockefeller Institute, who found that fatalities are not limited to pregnant rabbits but may occur in pseudopregnancy. From this he concluded that the hypothetic toxic factors in this disease cannot arise from the fetus or placenta. Demonstration by Anselmino and Hoffmann<sup>3</sup> that an excess of vasopressin is present in human eclamptic blood led to the hypothesis that the toxic factor in eclampsia is of pituitary origin. This hypothesis is supported by the fact that repeated injections of commercial vasopressin will produce eclampsia-like symptoms and lesions in laboratory animals.<sup>4</sup>

In order to settle these and other controversial questions, Dill and Erickson tested the effects of experimental renal ischemia in pregnant dogs. Nonpregnant females were used as controls. Renal ischemia was produced by the application of Goldblatt adjustable clamps to the renal arteries. Within forty-eight to 120 hours after relatively slight constriction of the renal arteries by this technic the pregnant dogs developed weakness, lassitude and convulsions and exhibited hypertension, hematuria, albuminuria and nitrogen retention. The symptoms deepened to coma, death occurring in from five to fifteen days. Control nonpregnant dogs often failed to show symptoms following mild renal ischemia, hypertension being observed only after the renal clamps had been further tightened.

Following the development of typical eclampsia, two of the Duke University dogs aborted. Rapid improvement and full recovery followed, except for a slight residual arterial hypertension. The significant appearance at autopsy in their eclamptic dogs is practically identical with that described in fatal human eclampsia.

Even more fulminating toxic symptoms were obtained by applying the same renal ischemic technic to pregnant rabbits. Death usually occurred within two to five days, with typical eclamptic lesions of parenchymatous tissues.

The Duke investigators believe that the physiologic and pathologic processes underlying their experimental eclampsia in dogs and rabbits are identical with those of human eclampsia. A study of the presumptive toxic

factor is now in progress in their laboratory, in the hope of developing a logical and effective therapy. The only fact definitely established by the Duke investigation, however, is their demonstration that a relatively slight interference with normal renal function is sufficient to cause a fatal toxemia of pregnancy in laboratory animals.

## SIGNIFICANCE OF URINARY AMMONIA

Although the acid-base equilibrium is first maintained by the buffers of the blood and other body fluids, the final removal of acid from the body is effected by the lungs, skin and kidneys. The expired air and the sweat are of peculiar significance as pathways for loss of metabolic acid, as all of the expired carbon dioxide and about half of the lactic acid of the sweat are removed without accompanying loss of base. In the kidney likewise there is a highly important mechanism for the excretion of acid without concomitant loss of fixed base, here it is the formation of ammonia from urea. The formation of this endogenous base in response to the administration of mineral acids was first noted by Walter in 1877. Magnus-Levy, in his classic monograph on diabetic acidosis, called attention to the augmented excretion of ammonia in the urine of such patients and suggested that the level of urinary ammonia might be used as an index of acid excretion. The fact that administration of sodium bicarbonate results in a marked diminution in the production of ammonia by the kidney has served to support further the view that there exists a close relation between acid excretion and formation of ammonia.

A recent statistical study<sup>1</sup> of the correlation between the volume, specific gravity, titratable acidity,  $p_H$  and urea nitrogen on a large number of samples of human urine shows a higher coefficient of correlation between ammonia production and titratable acidity than between ammonia and any of the other constituents determined. The lack of definite parallelism between ammonia and  $p_H$  was reaffirmed. The exact mechanism or stimulus which brings about the increase of ammonia is not so clear. It has been shown<sup>2</sup> that in the course of fasting the ammonia production is not strictly parallel to the increase in acid excretion but rather inversely proportional to the concentration of fixed base. Again, from a study of the so-called acidosis of pregnancy it was concluded<sup>3</sup> that the elevated urinary ammonia was a sign of decreased level of available fixed base rather than of increased acid excretion. In other words the formation of ammonia in the kidney is conditioned by the necessity on the part of the body to conserve fixed base. A sign of dissent with this point of view is contained in a recent report by Briggs,<sup>4</sup> who on the basis

of failure of prompt adjustment of ammonia to changes in urinary fixed base after forced breathing believes that the function of urinary ammonia is to protect the urinary passages from the acidity of the urine. According to this view it is the acid-base balance of the urine, not of the tissues, which governs the production of ammonia.

The recent studies in which newer experimental procedures have been employed and novel points of view developed have raised questions as to the exciting mechanism of the production of ammonia. The current basic conception has been changed little, if any, the variation in urinary ammonia follows the body's need for the excretion of acid with, at the same time, the maximum conservation of fixed base.

### Current Comment

#### BACTERIOLOGIC INVESTIGATIONS OF PUBLIC HEALTH SERVICE

The bacteriologic investigations of the United States Public Health Service are often overlooked because of the better known activities of this agency in more publicized fields. Most of the original research of the service along these lines was done at the Hygienic Laboratory, the name of which was changed in 1930 to the National Institute of Health. The work of this branch of the service has been recently summarized in a condensed but impressive fashion.<sup>1</sup> Especially noteworthy activities include the control of standards of biologic products for immunization and treatment, important work on disinfectants, especially with regard to fumigation and embalming procedures, and original investigations on encephalitis, leprosy, pellagra, plague, poliomyelitis and rabies, to mention only a few. A continuation of distinguished investigation in these and other fields may be confidently expected.

#### CLINICAL STUDY OF DRUG ADDICTS

As one part of the extensive studies on drug addiction at the United States Public Health Service Hospital at Lexington, Ky., recently discussed in *THE JOURNAL*,<sup>1</sup> Pescor<sup>2</sup> presents a statistical analysis of the information contained in the clinical records of more than a thousand admissions. Although addiction may occur at any age, the heaviest concentration of cases occurred in the decade between 20 and 30 and few became addicted after the age of 50. Thus there is greater potential danger of acquiring the habit in youth than in the later years of life. To the question as to why drugs were begun, the most common reply given was "curiosity and association with undesirable companions." Following this in order of frequency was the use of drugs "for the relief of pain or physical distress," "to sober up after alcohol sprees or to relieve hang-

over" and "relief of fatigue," also as an antidote for environmental distress. Morphine was the first drug used by the majority of patients, opium smoking and the use of heroin followed closely. Although the average period of addiction at the time of admittance was about twelve and a half years, five of the patients admitted addiction of forty years or more and one had used drugs continuously for fifty-nine years. About three fourths of the patients had previously attempted a cure, more than half of these having been enforced, or "jail house," cures. Such "cures" in general did not appear to be as effective as voluntary cures. The educational attainments of the patients were more or less comparable to those of the population at large. The occupational distribution revealed the highest concentration in the personal service classifications and the professional class. The majority of the addicts came from deteriorated and densely populated localities. The tendency to marital failure and inadequacy of social adjustment was strongly manifest. Dental difficulty of a type peculiar to addicts was found in practically every case. The majority of the patients made satisfactory social adjustments before but not after addiction. Finally it was noted that the "voluntary" patients were the least cooperative chiefly because of their insistent demands for release against medical advice.

#### SENATOR WAGNER INTRODUCES HEALTH PROGRAM LEGISLATION

On February 28 Senator Wagner of New York introduced in the Senate a bill for the carrying out of some of the phases of the National Health Program. In the proposed bill Senator Wagner offers a series of amendments to the Social Security Act calling for an expenditure of federal funds amounting to \$80,000,000 the first year with gradual increases over a ten year period for the purpose of establishing, expanding and improving state programs for "(1) child and maternal care, (2) general public health services and investigations, (3) construction of needed hospitals and health centers, (4) general programs of medical care, and (5) insurance against the loss of wages during periods of temporary disability." Senator Wagner said in an interview that it "should be clearly understood that the bill does not establish a system of health insurance or require the states to do so." Funds would be made available under this bill to "those localities and states which are in the greatest need of the services," the size of the grants being determined "on a variable matching basis, depending on the relative financial resources of the several states as determined by the per capita income of their inhabitants." It is not possible at this time to offer a complete analysis of the details of the proposed legislation. Obviously, it will be necessary for suitable committees of the Congress to give careful consideration to the proposals. While the sum announced—namely, \$80,000,000 annually—is not large as compared with an annual expenditure of \$850,000,000 ultimately proposed by the National Health Program, it represents nevertheless a considerable sum. Senators interested in an economy rather than a spending program have already announced opposition.

## AMERICAN MEDICAL ASSOCIATION STUDY OF MEDICAL CARE

### REPORT OF MIDDLESEX SOUTH DISTRICT (MASS) MEDICAL SOCIETY, BOSTON

The following report is based on the data recorded on the summary sheet of the Middlesex South District Medical Society. As indicated in the title, the Middlesex South District is not a county but a district society and, as stated in the summary sheet, no estimates of the population in this district can be made. The largest political unit included in this district is the city of Cambridge—a part of the metropolitan district of Boston. Some idea as to the population and economic status of the people in this district may be obtained from the following facts. Harvard University is located in Cambridge, and much of the surrounding area is urban residential districts, there are 169 industrial concerns in Cambridge, of which 143 are manufacturing plants which employ 20,753 workers.

In order to show the number of persons and organizations which contributed the information included in this summary, a list of the number of forms sent out and the number and the percentage of returns is given in table 1.

This table brings out the fact that a larger percentage of the health departments, the welfare and relief agencies, the hospitals, the nurses' organizations and the schools and colleges have contributed data, on which this report is based, than of physicians and pharmacists. Consequently, the statistics in this report are made up primarily of the figures recorded by those organizations. Therefore a summary of the data must present an accurate picture of the supply and need for medical care in this district, since it is not based on the experience of any one group of persons or organizations but on the experience of representatives of all persons who provide medical care and of practically every organization that arranges or furnishes medical care. The public health nurses, the welfare and relief agencies and the health departments are engaged in work that offers them every opportunity to discover persons unable to obtain medical care, so it is very improbable that any lack of medical care could have passed unnoticed by them.

A concise report on the amount of medical and surgical care furnished in 1937 is given in table 2. A study of this table will show that medical care is available to all economic classes, especially the indigent and low-income groups.

Table 2 shows that during 1937 a great deal of medical services, hospitalization, nursing services and medicines were furnished free or at reduced rates to a large number of persons in this area. For the indigent and the low-income group twenty-three clinics and outpatient departments furnished care at no cost or at reduced rates to persons eligible to receive such care. The colleges provided medical treatment for their students, so they did not need to obtain services from the clinics or outpatient departments. Since we have no figures on the number of persons in this district, it is difficult to determine the adequacy of medical care from the amount of medical care furnished.

From the data given on the lack or need of medical care it is possible to determine more specifically whether some persons were unable to obtain necessary medical care. Three physicians stated that they knew of some persons unable to obtain medical or dental services. The reason for one case was the inability to obtain free dental services. The other cases were due to overcrowding at clinics and inadequate hospital facilities for the poor. Comments from forty-four of the physicians accompanied the report. An analysis of these comments indicated that twenty-two of the physicians felt that there was an opportunity for every one to obtain services at the clinics if they were unable to afford a private physician. Too many of the patients accepted by the clinics could pay for their medical services. Since the physicians devote a portion of their time in furnishing free services at the clinics, either some arrangement should be made to eliminate the patients capable of paying regular fees or physicians should be partially remunerated for their services at the clinics. Three physicians believed that it was the high cost of surgical treatment that caused so many persons with low incomes to feel that they could not afford medical care. Four physicians thought that the most important factor in the lack of medical care among the low-income group was lack of information on the availability of medical care. Two physicians were in favor of compulsory prepayment plans for medical care, or sickness insurance for the low-income group, since this group seemed to be incapable of making provisions to pay for medical care. A few physicians thought that it was the high cost of laboratory tests and x-ray treatments that caused so many people to think that medical care was beyond their ability to pay. To alleviate this condition they recommended free diagnostic centers, maintained by the government.

One hospital reported that 285 patients were refused admittance as bed patients because they were not able to pay for hospitalization. The other sixteen hospitals reported that they had not turned away any patients. The comments from eight hospitals on the methods to improve the supply of medical care may be summarized as follows. There is a great need for a "filter system" that will prevent people who are able to pay for medical care from taking advantage of the free services provided in the outpatient departments and clinics. The local governmental agencies should pay for hospitalization and medical services required by people who are financially unable to pay for such services themselves, after their indigence has been established by a thorough investigation.

The hospital outpatient departments turned away fifty-eight persons because they were not eligible to receive care there. Some were referred to physicians, some to the Veterans' Bureau and the remainder to the eye clinics.

The health departments stated that 15,583 persons in need of medical care were reported to them. These people needed treatment for tonsils, adenoids, teeth, ears and eyes, and orthopedic therapy. It was stated that they were unable to obtain the necessary treat-

ments because there were inadequate free services available. If these people did not receive medical care the responsibility must rest with the local governments, since the health departments had been informed of their need and of their inability to pay for the necessary services. The health departments also reported that 13,585 people had requested medical services from

TABLE 1—Distribution of Forms

Schools	70	64	91
Colleges	6	6	100
Other organizations		22	
Pharmacists	196	46	23

\* The information supplied by the dentists in this district is included in the Suffolk district report.

them and that the necessary services could not be obtained for 4,801. The reasons for this inability were not given. Five health departments made statements as to what they considered was needed to meet the need for medical care. Three of the health departments stated that all persons who applied for medical care were getting the necessary care through the cooperation of the public health nurses, the private physicians and the public welfare boards. One health department thought that more clinics for tonsil and eye cases were needed. Another stated that outside of the communicable diseases, for which adequate care was provided, they had no information on need for medical care.

The welfare and relief agencies reported that they knew of no persons who needed medical care that could not obtain the necessary care. If the 20,384 persons reported by the health departments as unable to obtain medical, dental, hospital or nursing services were referred to the welfare and relief agencies or the public health nurses, then they evidently received the necessary services since the welfare and relief agencies and the nurses stated that they were able to arrange or provide medical services in every instance in which they found a need for such services. There appears to be a lack of cooperation and agreement between the health departments and the welfare and relief agencies and public health nurses in this area. The comments from the welfare and relief agencies indicated, however, that the people they dealt with might not be furnished with all the medical care they needed. They stated that they lacked funds to provide dental care, eye examinations and glasses to some of their clients. They also believed that many people with low incomes waited too long before obtaining necessary medical or dental care but, in their experiences, they knew of no cases in which medical or dental care could not be obtained if requested.

The public health nurses reported that they had not found any person in need of medical care who could not be furnished with the necessary care. The general experience of the nurses, as stated in their comments, was that they occasionally found a person in need of medical treatment who had made no attempt to obtain such treatment because he felt that he could not afford the cost. In such cases the nurses experienced

no difficulty in furnishing medical care. The nurses have always found the private physicians and the welfare and relief agencies willing to cooperate with them in their work. To the nurses the big problem is economic—not medical—since so many people have such low wages that they are unable to maintain a standard of living that is conducive to good health. These same people are not eligible for governmental aid in obtaining necessary goods and services, which they need as much as the totally indigent persons who are cared for through the use of government funds.

In the elementary or secondary schools the examinations provided by the school boards revealed that 19,237 pupils were in need of medical or dental care in 1937. Of this number 2,000 were unable to obtain the recommended care because their parents were unable to pay for it or because there were not enough free clinics where the treatment could be obtained. The comments from the schools were, in general, that the parents cooperated very well with the recommendations of the school physicians, although there was some difficulty in obtaining glasses and dental care for many of the children whose parents lacked the funds to pay for such services and items themselves.

The colleges and universities provided their students with the necessary medical care through their infirmaries and staff of physicians.

TABLE 2—The Amount of Medical Care Furnished in 1937 According to the Persons and Organizations That Provided It

	No.	No. of Beds	Pay and Part Pay Patients	Public Charges	Free Patients
Hospitals	17	2,979	3,355	3,771	3,929
Patient days			417,094	58,936	53,463
Outpatient clinics	9	24,454		61,374	
departments and					
Public health nurses	51	84,471		Percentage of Visits Made Without Charge 30.5	
Pharmacists	46	2,810		No. of Prescriptions Provided at Cost or Reduced Rates 65.0	
Physicians	140	16,090		Total Number of Persons Who Received Free Care in Home or Office 115	
Per physician				Total Number of Hours Devoted to Care of Free Cases in Clinics 27,581	
					Number
Clinics maintained by the health department					11
Clinics maintained by welfare and relief agencies					3
Schools which have health supervision					61
Colleges which have health examination and supervision					0

The number of free prescriptions furnished by the pharmacists has been given in table 2. The pharmacists' ideas on the methods of supplying medical care is presented in the following summary of their comments. The public is well supplied with medical care and the physicians and the pharmacists have contributed more than their share of free services and medicine in making this care available to the poor. The local governments should apportion funds to be used to pay for medicine prescribed by the physicians to patients who are in the low-income class, as well as for the indi-

gent The indigent should have the privilege of calling their own physician and of obtaining prescribed medicine at their local pharmacy

The study on the supply of medical services in industrial plants was made with the aid of Mr Winthrop Taft of the Harvard Business School, who was employed to collect the data and information from the 169 industrial concerns in this district This group is made up of 143 manufacturing plants, and the remaining twenty-six are warehouses, banks and small stores

The 143 manufacturing plants employ 20,753 persons Of this number 51 per cent of the workers receive some medical attention through their employment, but only seventeen of the 143 plants have the services of a physician available or on call Nursing services are available in twenty-one plants, which includes 64 per cent of the 20,753 workers Seven of the plants require annual physical examinations, and eighteen plants give physical examinations when the workers are hired Forty-four plants, employing 82 per cent of the total workers, maintain first aid rooms, but there is one plant employing 200 people that does not provide even a first aid kit, although the law requires that all plants employing 100 persons or more must provide first aid rooms The amount of medical care provided by the twenty-six warehouses, banks and stores is negligible, as no establishment employs as many as 100 persons

The following recommendations concluded the report on medical care in industrial concerns

It is recommended that

- 1 Medical supervision of plant employees be increased
- 2 Annual physical examinations be increased
- 3 Health records be increased
- 4 Cambridge physicians be used more extensively (in order that a doctor would have personal interest in a plant rather than being representative from an insurance company or hospital)
- 5 More dental clinics be fostered in the community where dental care can be given within the patient's means
- 6 Health education be increased

The members of the Middlesex South District Medical Society's Committee on the American Medical Association's Study of the Need and Supply of Medical Care made an appraisal of the comments submitted by the physicians and pharmacists concerning the need of medical care and the methods that they believed should be considered in meeting this need Because this committee is more qualified to interpret and explain the comments of the local physicians and pharmacists, its report is printed below

There is little doubt in regard to the unanimous attitude of the doctors that they are making every reasonable attempt to provide medical care for all who need it This desire, however, is tempered as well as at times tried because of certain disturbing conditions The first of these is the obvious attempt on the part of some to secure medical attention gratis when a reasonable fee could be paid The matter, however, is not simply that of trying to distinguish patients on the basis of minimum financial ability Other things enter the picture For example, a number of doctors have commented on the expense of laboratory, x-ray and other special services needed for diagnosis The expense of these seems at times to be out of proportion to the small income of the patient, since such services increase substantially the total cost to the patient Even more serious is the public relations aspect as indicated by the comment "I observe that clinic patients can obtain

laboratory and x-rays for a lower price than private patients that I send to hospitals for this work This discourages the pay patients to come to me and many go directly to clinics the next time they require such work I believe that a set price should be established for such work" Other comments seem also to point toward a potential case of carelessness with which the social services may be charged when deciding, without careful inquiry, to send patients where they may obtain free advice

Another comment made by many physicians is that the very poor have far better medical assistance than those wage earners whose incomes are in the lower brackets Often these patients have to bear the full cost of medical care simply because they are receiving a nominal income This serious problem appears to revolve about the question of how in an economically and socially wise manner medical care may be provided for these people Some of the replies reflect a hasty opinion that the government might as well provide the cost of this service, implying that the government has already wasted more than enough to cover all such needed help to the citizens This position, however, appears to beg the question, since there are many individuals who are either too proud to come or who because of a technical fact of small income cannot come under this government control The doctors making the comment of "let the government do it" appear to forget that such a move on the part of the government represents a first step toward full government control of medical services to the whole population

A number of the comments reflect the well known fact that in many instances the less well-to-do and the poor are as inefficient in caring for their health as they are in their economic position Lifting an individual out of trouble with regard to his or her ailment consequently does not lead necessarily to a permanent cure

On the other side of the picture there is the question of how much time, energy and also out-of-pocket expense the doctors should be expected to provide Many of the comments reflect the ever present struggle to earn a living The thought that this might be avoided through some kind of sovietized medicine recalls once more the dread of politics and lowered standards

Turning now from the point of view of the doctors to that of the pharmacists, we find some interesting suggestions These concern the patients from the lower economic classes The pharmacists comment that the socially poor tend to ask for medical care in the case of trivial ailments This observation is coordinate with that of the doctors, indicating that the fundamental trouble with many of these people is a poverty in understanding and wisdom as well as that of pocketbook and social position Also, in the minds of the pharmacists, many clinics are too hurried for full diagnosis

There is no doubt that the pharmacists are anxious to cooperate with the doctors The service, however, which they render to indigent and low income groups of customers is given more from a feeling of business charity than is true of the gratis service of doctors which originates in knowledge that they are following a profession

There is apparently the serious difficulty of fee and public payment plan between politicians, doctors and pharmacists in the case of some charity patients This would lead one to inquire whether for the poorer patients the whole relationship between doctors, patients and pharmacists, with the politician on the side, ought

not to be reviewed very carefully by physicians in order that they might fully understand one phase of public relations in public health work.

With reference to the special instances, one pharmacist indicated that the physicians whose prescriptions he fills are not always too thoughtful regarding the expense of the drugs prescribed. This pharmacist comments "After forty years in the business I am convinced that the patient is asked to pay too much for specialty prescriptions. The physician writes for some specialty either not knowing the cost or at least not telling the patient, and the result is that the patient thinks he is being robbed."

In summary it may be said that both doctors and pharmacists are vitally interested in the health of the community from the point of view of a wholly sound and highly professional attitude. This is well known

There appears to be in the situation, however, some difficult problems. These center about the means of providing medical care for the lower income groups and surgical care for the very poor according to some plan which will provide the attending physician with a financial return sufficient to enable him to maintain self respect among his fellows. There is, in addition, the serious problem of coordination between doctors and pharmacists. Possibly doctors have been too inclined to take the pharmacists for granted and too ignorant of the business side of the drug store. Finally, the comments in many instances hint at unsolved problems of human relations. These problems should be discovered, their causes disclosed and their cure begun. Only in this way can the medical profession through its own activity avoid what is believed to be the very bad alternative of governmental control.

## THE COMMONWEALTH FUND AND EXTENSION TEACHING

*Abridgment of Report on Postgraduate Study and Extension Teaching from the 1938 Annual Report of the Commonwealth Fund, New York City*

The Commonwealth Fund encourages postgraduate study in several ways by giving fellowships for study at selected medical schools to physicians in certain parts of the country through the Divisions of Rural Hospitals and Public Health, by subsidizing the development of university facilities for postgraduate teaching and by joining with state medical societies and health authorities in setting up extension courses which take instruction to the doctor in his own bailiwick.

Whatever the content, the division believes that postgraduate study is rewarding if it brings the student into close personal touch with an outstanding and modern-minded teacher—discipleship plays a large part in medical education—if it helps him to make the best use of books and journals, and if it gives him a sound approach to diagnosis.

In the public health program, emphasis falls on general brush-up courses for physicians practicing in the states in which the fund is subsidizing public health work, and in some instances in neighboring states. To meet the preferences of such men, the four month courses hitherto offered at Vanderbilt have been broken up into four units of a month each, to be taken separately at the physician's convenience. It is understood, however, that the month in physical diagnosis and internal medicine is to come first and is to serve as a foundation for the courses in surgical diagnosis, obstetrics and pediatrics. A similar arrangement is in force at Harvard for postgraduate students from the four northern New England states.

Postgraduate teaching under university auspices may be done either on the campus or in the field. On the initiative of its late president, L. D. Coffman, the University of Minnesota recently found a fresh way to lure busy men and women back to the campus. A building was put up for their special use, and a schedule of week-long courses in many fields keeps this dormitory-teaching center in constant use. All the circumstances favor serious and concentrated work. Courses in medicine form an essential part of the plan, physicians enrolled readily for the first of these courses and in some instances came back again and again for more

The fund has made it possible for the university to employ a full-time director to develop these medical courses to their fullest possibilities.

At Tulane University, where resident postgraduate medical instruction is of long standing, the fund has helped to set up a division of extension education which, in collaboration with various professional agencies, offers instruction in the field. This division has arranged courses in pediatrics and syphilology which have already reached several hundred physicians in Mississippi. Here the unit of instruction is a series of lectures every day for a week, but some of the best teaching is done by the instructor in consultation with individual physicians outside the regular sessions. The state medical association and the state department of health in Alabama have now joined in asking that similar courses in internal medicine be offered in that state.

Meanwhile, field instruction in obstetrics, following the pattern used with such success in Virginia and Mississippi, has been continued for a second year in Tennessee with a full-time instructor employed jointly by the state medical association, the state health department, the two medical schools and the Commonwealth Fund, and a similar arrangement was launched during the year in Oklahoma. Both projects have been highly successful. Something over 1,100 physicians have been enrolled in Tennessee, and the initial response in Oklahoma surpassed all expectations. In one circuit in rough, hilly country in Oklahoma, a doctor distinguished himself by driving eighty miles from his home to the nearest center of instruction to make up for a session which he had been forced to miss because of an emergency call.

The scholarship plan by which the fund seeks to steer promising medical students into rural practice has now carried thirty-three young men through medical school and into small-town offices, with seventy-eight more on the way.

Medical education underlies the fund's field programs in public health, rural hospitals and mental hygiene. When the sums earmarked for this purpose are brought together from the budgets of these programs and added to those appropriated directly in the form of special grants, they total, for the year just ended, approximately \$375,000.

## GRADUATE MEDICAL EDUCATION

A PROGRESS REPORT OF THE FIELD STUDY ON GRADUATE MEDICAL EDUCATION IN THE UNITED STATES  
BEING CONDUCTED BY THE COUNCIL ON MEDICAL EDUCATION AND HOSPITALS

## OKLAHOMA

In 1925 the director of the Extension Division of the University of Oklahoma adapted North Carolina's plan for continuing the training of practicing physicians to the needs of Oklahoma. The dean of the University of Oklahoma School of Medicine became interested and was appointed the first chairman of a committee of three, with the superintendent of the university hospital and the professor of internal medicine of the school of medicine as members. The director of the extension division served as an ex officio member. A budget of \$1,500 was appropriated by the president of the university, although it was proposed that the extension programs be self supporting. A field director was appointed and an out of state pediatrician who was experienced in conducting graduate courses on a circuit basis was engaged. County medical societies throughout the state were presented with the plan and voted on its acceptance. Six circuits of seven centers each were set up the first year, and within fourteen months the state was covered, and slightly more than 1,100 physicians had subscribed for the series of twelve lectures. A registration fee of \$30 was charged.

The extension division of the university continued to administer the graduate program, publicize the courses and organize the instructors' itineraries. Physicians who gave the instruction were engaged by the university. The extension division later provided for the financing, prepared the announcements and arranged for enrolment of practicing physicians.

In 1926 other courses were given in internal medicine, a series of nine lectures with clinics and consultations in seven teaching centers.

The course in internal medicine was repeated in 1927 with another guest lecturer, who gave three hours of lectures and clinics weekly for nine or ten times. An organizer from the university's extension division assisted each county society which elected the program. The fee for this series was \$35. A short course in the examination, diagnosis and treatment of tuberculosis was arranged in each of the three state tuberculosis sanatoriums. Illustrated lectures, laboratory demonstrations and clinics were given by the hospital personnel for one week. Each class was limited to twenty physicians, the fee was \$7.50. Demonstrations and lectures in physical therapy were conducted for one week at the medical school by an out of state physician, with the use of the facilities of the university hospital.

In 1928 one week intramural courses in surgical diagnosis and in medical diagnosis were held in Oklahoma City, while the instruction in tuberculosis was repeated in one of the state sanatoriums and courses in physical therapy and surgical diagnosis were given in Tulsa.

Intramural courses designed for practicing physicians were given in obstetrics, gynecology, pediatrics, urology and eye, ear, nose and throat during 1929. Five or six out of state specialists constituted the faculty for the week of instruction in each subject. The enrolment for each course was limited to forty physicians. Fees were \$35. In addition the extramural course in internal medicine was repeated in six teaching centers of the state.

The graduate activities of the first five years resulted in a deficit greater than the university could assume. The Oklahoma State Medical Association therefore donated approximately \$700 in order that the field director might continue his work. Full time instructors were discontinued and teams of three prominent guest speakers were invited to visit the state for a week's period. Each of these instructors gave six lectures to any county medical society that would pay the traveling expenses. Attendance varied at these meetings from twenty-five to 250 physicians, depending on the number of physicians practicing in the sections visited.

In 1929 officers of the state medical association proposed to the extension division of the university that medical and surgical motion picture films be distributed among the county medical societies of the state. Approved films were purchased by the state association, the extension division serviced them, arranged for booking and distributed them to various county societies. The only charge to the local societies was for transportation of films to and from the university. When local operators were not

available, they were provided for a small fee. The films were widely used throughout the state and at the University of Oklahoma School of Medicine. In 1933 films were shown in seventy-seven towns and in all but two cases were without expense to the state medical association.

During the period 1929-1930 the University of Oklahoma provided the otolaryngologists and ophthalmologists in two centers of the state with one week of instruction, including pathologic anatomy with material for dissection. Again prominent teachers visited the state and supervised dissections. Two graduate physicians were assigned to each cadaver. University hospitals provided facilities. A fee of \$50 was charged, thus providing competent instruction. Groups of from twenty to sixty physicians enrolled and the venture proved successful financially.

From 1930 to 1933 the practicing physicians of the state were again provided with prominent out of state instructors, who gave intensive intramural courses at Oklahoma City and one circuit course throughout the state. In 1931 there were an intramural course and a series of circuit courses which were held in six centers of the state. In 1932 two courses were given in each of the eleven centers as well as one intramural program on degenerative disease.

The state medical association appropriated sufficient funds in 1933 for four courses of instruction, one each in obstetrics and gynecology, in surgical diagnosis, in traumatic surgery and in degenerative disease. Thirty-six out of state speakers participated in these courses, which were given in twenty-six centers of the state. Twenty-eight in state physicians also participated. Cancer teaching clinics were organized in several parts of the state and were attended by 1,137 physicians.

There were approximately 1,900 physicians who received instruction in one or more of the subjects given during 1933. The state medical association spent \$700, the state of Oklahoma appropriated \$1,431 and the physicians paid fees totaling \$5,065. The deficit was made up by the extension division of the university.

The courses were discontinued at this point because the governor of Oklahoma withdrew financial support from the extension division of the university. In addition, cultists attempted to gain entry to the state courses in October 1933, and three years passed before it was possible to resume the graduate program which had had such an auspicious beginning.

At this time a joint committee composed of representatives from the state medical association and the faculty of the school of medicine developed a speakers' bureau. The university extension division issued a bulletin containing the names of 100 Oklahoma physicians and the subjects on which they would speak. The secretary of every county medical society was provided with a copy so that some graduate training might be continued to this extent.

In 1936 the state association's special committee on postgraduate medical teaching again planned an extensive program of graduate instruction. The committee was composed of three members with Dr. Henry H. Turner as chairman. Three out of state speakers were engaged to give courses in cities in the western half of the state. Subjects of general interest to practicing physicians were included at this time.

In 1937 the request of the postgraduate committee of the state medical association for an appropriation of \$2,000 was granted in order that a state wide postgraduate program in obstetrics might be financed. The Commonwealth Fund of New York made a very substantial contribution and the Oklahoma Health Department also assisted financially. Under the plan ten lectures, clinics and demonstrations in obstetrics would be given at weekly intervals in county seat towns or centers where physicians customarily met for county medical society meetings. A full time instructor was engaged and a field director familiar with the state employed to make the preliminary arrangements. The plan is similar to the one which operated so successfully in Tennessee.<sup>1</sup>

<sup>1</sup> Graduate Medical Education Tennessee J A M A 111 725 (Aug. 20) 1938

The state was divided into nine teaching circuits. Five cities in each circuit were selected as teaching centers. The first course began on April 4, 1938, in the northeastern part of the state. By November 15 three circuits had been completed and 244 physicians in thirty-one counties had received instruction. Enrolment for the fourth circuit totaled 115. It is expected that the nine circuits in the state will be covered by January 1940.

In each teaching center a clinic chairman arranges for clinics and for consultations whenever the latter are requested by local physicians. A record of attendance is kept. The registration fee is \$5 for the series of clinics, which include manikin demonstrations. The fact that the success of the clinic depends largely on the cooperation of physicians in the community makes the program a responsibility of the local profession thus assuring keen local interest. A minimum of fifteen physicians must register in a center before a course may be given.

In addition to practicing physicians attending obstetric lectures and clinics, nurses who assist local physicians are invited to listen to the instruction. Superintendent nurses of obstetric hospital wards are invited also, as well as nurses employed full time by county health units. No fee is charged nurses for this training, since the course is arranged primarily for physicians.

The committee on postgraduate medical teaching has an advisory committee of six members with the commissioner of health of the Oklahoma Health Department and the dean of the medical school as members. The health department has cooperated by rendering financial assistance. Mimeographed notes of the lecturers are prepared by the committee's secretary. These are bound and distributed to physicians on completion of the course. The medical school has contributed equipment which is used in illustrating the lectures. It is estimated that the total expenditure for this type of instruction will approximate \$19,500 to provide for the salary and traveling expenses of the clinical instructor and field director and the salary of a full time office secretary in addition to miscellaneous expenses for supplies and equipment. The treasurer of the state medical association disburses the funds on the approval of vouchers by the committee chairman.

The Oklahoma Health Department began a series of post graduate courses in venereal disease in October 1938. These courses are given one day each week for five times without cost to physicians. They are conducted by a member of the health department and will be given until the entire state is covered. The president and secretary of each county medical society are notified when lectures are to be held and are responsible for making the local arrangements. Instruction is limited to practicing physicians only. Thus far, four counties have been visited and 157 physicians in these areas have attended the lectures.

The Oklahoma City Clinic sponsored by the Oklahoma City Clinical Society has been given each year since 1930 by a group of physicians in the Oklahoma County Medical Society. The clinical society consists of 150 members of the 290 in the county medical society, each member contributing \$10 a year. This organization brings to Oklahoma City sixteen prominent guest speakers, who are given traveling expenses only. The meetings, are of four days' duration and consist of a series of lectures and round table discussions, which are held in a local hotel. The director of clinics, at present Dr. Wendell Long, has charge of local arrangements. Commercial exhibits, thirty in number, aid in financing the clinical conference. The number of physicians who have registered has increased from 385 in 1933 to 522 in 1937. Approximately 80 per cent of those who attend are from Oklahoma and the remainder are distributed throughout the ten states in this section of the country. Registration fees are \$10. The conferences are announced in state medical journals and by letter to approximately 13,000 physicians.

The Commonwealth Fund of New York offers eight scholarships each year to practicing physicians of Oklahoma who desire to spend three or four months of graduate study in a medical center. Each applicant is interviewed by a member of the staff of the Commonwealth Fund. Physicians who are selected are given a small stipend and are provided with traveling expenses and tuition. This plan, which has operated so successfully in other states, was begun in Oklahoma in 1938.

There are 2,364 physicians in Oklahoma, 1,457 of whom are members of the Oklahoma State Medical Association.

## OFFICIAL NOTES

### ADDRESSES BY OFFICIAL STAFF

DR PAUL C BARTON

March 8—Interprofessional Relationship Committee of the Hennepin County Medical Society, Minneapolis

DR W W BAUER

March 6—Woman's Club, People's Church, Chicago

March 13—Marquette University, Milwaukee

March 20—Men's Civic Club, Antioch, Ill

March 21—Young Women's Club, Bryn Mawr Church, Chicago

DR MORRIS FISHBEIN

March 6—Southeastern Surgical Congress, Atlanta, Ga

March 10—Woman's Auxiliary, Milwaukee County Medical Society, Milwaukee

### RADIO BROADCASTS

The fourth series of programs broadcast in dramatic form portraying fictitious but typical incidents of significance in relation to health by the American Medical Association and the National Broadcasting Company, entitled "Your Health," began Wednesday October 19 and will run consecutively for thirty-four weeks. The program is broadcast each Wednesday over the blue network of the National Broadcasting Company at 2 p m eastern standard time (1 p m central standard time, 12 noon mountain time, 11 a m Pacific time).<sup>1</sup>

These programs are broadcast on what is known in radio as a sustaining basis, that is, the time is furnished gratis by the radio network and local stations and no revenue is derived from the programs. Therefore, local stations may or may not take the program, at their discretion, except those stations which are owned and operated by the National Broadcasting Company.

The next three programs to be broadcast, together with their dates and their topics are as follows:

March 8 Water Waste and Sanitation

March 15 Guarding Fresh Foods

March 22 Auditing the Health Record.

<sup>1</sup> Owing to program conflicts there will be no Chicago broadcast of the network program. Instead a recording of the program will be broadcast over station WENR at 8 p m each Wednesday. This recording will be an identical rebroadcast of the network program broadcast earlier the same day.

## MEDICAL LEGISLATION

## MEDICAL BILLS IN CONGRESS

*Bills Introduced*—S 1383, introduced by Senator Brown, Michigan, and H R 4496, introduced by Representative Lesinski, Michigan, propose that no citizen of any foreign country the boundaries of which touch the boundaries of the United States shall be permitted habitually to cross the international boundary line for the purpose of seeking employment or engaging in any employment, vocation or trade in the United States S 1557, introduced by Senator Shipstead, Minnesota, proposes to enact a National Epilepsy Research Act This bill proposes to create in the United States Public Health Service a National Epilepsy Institute to conduct researches, investigations, experiments and studies relating to the cause, diagnosis and treatment of epilepsy to assist and foster similar research activities by other agencies, public and private, and to promote the coordination of all such researches and activities and the useful application of their results, with a view to the development and prompt widespread use of the most effective methods of prevention, diagnosis and treatment of epilepsy This bill is modeled closely after the National Cancer Institute Act S 1563, introduced (by request) by Senator Andrews, Florida, proposes to provide payment of pensions and increase in pensions to all veterans in all wars, their widows and dependents and certain peacetime soldiers The word "veteran" is defined in the bill in such a way as to exclude contract surgeons of the Spanish-American War H R 4421 and H R 4422, introduced by Representative Bloom, New York, propose, respectively, to establish a chiroprap corps in the Medical Departments of the Navy and Army H R 4425, introduced by Representative Cochran, Missouri, proposes to provide for reorganizing agencies of the government The bill does not provide for the creation of a federal department of health nor will the establishment of such a department be possible under the provisions of the bill if it is enacted H R 4427 introduced by Representative Green, Florida, proposes to authorize an appropriation of \$1,550,000 to construct a marine hospital in Florida on a site to be selected by the Federal Board of Hospitalization

## STATE MEDICAL LEGISLATION

## Alabama

*Bills Introduced*—S 115 proposes to require a physician diagnosing or treating a case of syphilis gonorrhea, chancroid, lymphogranuloma inguinale or granuloma venereum to report the facts immediately in writing to the county health officer S 116 proposes to authorize a county health officer (1) to require all persons infected with a venereal disease to undergo treatment therefor and (2) to isolate or quarantine persons infected with venereal disease and to commit to jail for treatment persons refusing to take or continue treatments

## Arizona

*Bills Introduced*—H 209 proposes to require every physician or other person engaged in the prenatal care of a pregnant woman or attending her at delivery, to obtain a specimen of her blood not less than ten days after the first professional visit and to submit that sample to an approved laboratory for a standard laboratory test for syphilis S 165 to amend the naturopathic practice act proposes to authorize the issuance without examination of a license to practice naturopathy to any person who has practiced naturopathy in the state for at least three years prior to January 1, 1939 provided application is made within sixty days after the date this bill becomes a law and is accompanied by a fee of seventy-five dollars H 249 proposes (1) apparently to repeal all existing law with respect to the practice of the healing arts (2) to create a board of examiners in the healing arts and (3) to prohibit the practice of any branch of the healing arts unless licensed by this board The board in the healing arts is to consist of one doctor of medicine, one osteopath, one chiropractor and one naturopath The bill proposes that any person practicing more than one branch of healing is to be required to obtain a certificate of

license for each branch so practiced The bill then attempts to define the practice of medicine, the practice of osteopathy, the practice of naturopathy and the practice of chiropractic The practice of medicine is defined "as a system of treating the abnormalities of the human mind and body by all forms of materia-medica and surgery" Naturopathy is defined as "a system of treating the abnormalities of the human mind and body by all forms of physiotherapy including the use of physical, electrical, hygienic and sanitary measures incident thereto, and does not include materia-medica or surgery" It would seem, therefore, that a doctor of medicine would be limited by a license to practice medicine to the use of "all forms of materia-medica and surgery," and that if he desired to use any form of physiotherapy it would be necessary for him to be licensed also to practice naturopathy The bill proposes to permit all licentiates to use the title of doctor or physician, to give all licentiates equal rights and privileges in all city, county and state institutions, agencies, institutions or hospitals deriving any support from the public funds and to give them equal rights and privileges under the workmen's compensation act and all health laws

## Arkansas

*Bills Introduced*—S 242 proposes to exempt from the payment of any privilege or occupation tax levied by any city or town which does not maintain a free medical clinic any physician whose services are largely given to the care of the indigent sick S 308 proposes that when any state agency empowered to issue or revoke any license refuses to issue or revokes a license the agency must make a report, setting forth the grounds for its action and, on request of the aggrieved person, must transmit the record to the appropriate chancery court H 366 proposes to create a state hospital board to be composed of the secretaries of the Medical Examining Board of the Arkansas Medical Society, the Eclectic Medical Examining Board, the Homeopathic Medical Examining Board, the Osteopathic Examining Board and the Chiropractic Examining Board This board is to require the registration of every hospital in the state and is to charge each hospital an annual registration fee of not more than \$5

*Bill Passed*—S 304 passed the senate February 21, proposing to classify as an investment company a person or organization issuing any form of contract or certificate to furnish hospitalization and/or medical care at a future date and to require such persons and organizations to obtain a permit from the Securities Division of the Bank Commission to file reports, to submit to examination and to pay similar fees therefor as is now required by law of all other investment companies

## California

*Bills Introduced*—A 2112 proposes to create a State Board of Eugenics, which is to be authorized on the application of the superintendent or warden of any state institution, to order the sexual sterilization of particular inmates of state institutions Apparently sterilization may be ordered when any inmate, if released without sterilization, would be likely to procreate a child or children who would have a tendency to serious physical, mental or nervous disease or deficiency A 2338 proposes to create seven crippled children hospital districts in the state, each district to provide special care and treatment, transportation and physical rehabilitation for physically defective and handicapped persons under the age of 18 A 2494 and A 2501 proposes to authorize the organization of corporations to write insurance against the need for medical and hospital services The bill apparently contemplates that a company so organized may provide medical services through licensed physicians in its employ A 2585, to supplement the Business and Professions Code, proposes to enact a massage, electro physiotherapy practice act and to create a state board to examine and license persons applying for such licenses Apparently licentiates of the board are to receive one of two types of licenses (1) a license to practice suggestive therapy, physiotherapy or magnetic healing and (2) a license to practice massage Swedish movements, medical gymnastics, and electro, hydro vibro helio, thermo, zone or mechano therapy The bill

defines physio therapy as the "treatment by mental impression or suggestion" A 2764, to amend the provisions of the Business and Professions Code relating to ophthalmia neonatorum, proposes that it is to be the duty of the attending physician where a child develops ophthalmia neonatorum within two weeks after birth to administer silver nitrate and to report the case within twenty-four hours after knowledge to the appropriate local health officer A 2745, to supplement the Business and Professions Code, proposes to permit any person whose license has been revoked to file an action in the superior court in the county in which he resides to determine all questions of law and fact pertaining to the revocation and to give that court full jurisdiction in the matter, provided that action is instituted in that court within sixty days after revocation of the license A 2436, to amend the law approved May 3, 1933, requiring the use of materials and supplies substantially produced in the United States in public works and for public purposes, proposes that the act shall not apply to medical and surgical instruments scientific equipment, microscopes, lenses, or instruments used for scientific or medical research

#### Colorado

*Bill Introduced*—S 332 proposes to restrict licensure in medicine, chiropractic, chiropody, mid-wifery or any of the healing arts to citizens of the United States

#### Connecticut

*Bills Introduced*—S 290 proposes to prohibit any hospital receiving a state appropriation from requiring or permitting any female nurse to work more than eight hours in any one day, nor more than forty-four hours in any one week H 464 proposes to amend section 3 of the charter of the Connecticut State Medical Society so as to provide that the house of delegates shall be composed of (1) the president, president elect, treasurer and secretary, (2) delegates to be elected annually by the several county medical associations, and (3) eight councilors to be elected from time to time as provided in the charter H 845 proposes to create stated persons a body politic and incorporate by the name of The College of Natureopathic Physicians The corporation's object is to be instruction in the principles, practice and theory of naturopathy and the corporation is to have the right to establish and maintain hospitals, sanatoriums, infirmaries and clinics and to award the degree of Doctor of Natureopathy to such persons as it deems entitled thereto H 1009, to amend the medical practice act, proposes apparently to provide for an eclectic medical examining board H 1025 proposes to make it an offense punishable by a fine of not less than \$500 for any institution receiving state aid to interfere or attempt to interfere with a patient in determining what physician shall attend him within the institution

#### Delaware

*Bill Passed*—S 27 passed the Senate February 23, proposing to require every physician attending a pregnant woman to take or cause to be taken a sample of her blood at the time of the first examination and to submit that sample to an approved laboratory for a standard serologic test for syphilis

*Bill Introduced*—S 57 proposes to repeal the laws relating to the Delaware Commission for the Feeble Minded and to create a Delaware Commission for the Mentally Deficient, which is to have jurisdiction and control over the Home for the Mentally Deficient

#### Georgia

*Bills Introduced*—S 139, to amend the osteopathic practice act, proposes to require an applicant to be a graduate of an accredited high school, to have completed not less than two years of college work "according to the Carnegie units, in an approved college of arts and sciences," and to have obtained a diploma from some legally incorporated and reputable school of osteopathy requiring a course of study of not less than four terms of nine months each Apparently the present osteopathic practice act imposes no educational qualification other than graduation from an osteopathic school requiring a course of study of at least three terms of nine months each H 399, to supplement the workmen's compensation act, proposes to make compensable disability arising from some twenty-five stated occupational diseases

#### Idaho

*Bills Introduced*—S 144, to amend the osteopathic practice act, proposes to make it "unlawful for any osteopathic physician to use the word 'doctor' or any abbreviation thereof in any advertisement or sign after or before his name, or in connection with his practice without adding the words 'osteopathy,' 'osteopath' or 'osteopathic physician' thereto" H 253 proposes, as a condition precedent to the issuance of a license to marry, that each party to a prospective marriage present a physician's certificate or a certificate from the Commissioner of Public Welfare that he or she is free from feeble mindedness, insanity or venereal disease in a contagious stage The bill proposes to limit a physician to \$2 for executing such a certificate and making the necessary tests

#### Illinois

*Bills Introduced*—H 224 proposes to appropriate \$1,000,000 for the erection and operation of a state hospital for the care and treatment of poor persons affected with tuberculosis H 230 proposes to prohibit the employment or continuance in employment of a food handler unless he possesses a certificate from a licensed physician dated within the preceding ninety days certifying that he is free from communicable disease H 282 proposes to enact a separate chiropractic practice act and to create an examining committee to examine and license persons to practice chiropractic The bill defines chiropractic as "the science of palpating and adjusting the articulations of the human spinal column by hand only" H 293 proposes to enact a separate osteopathic practice act and to create an examining committee to examine and license persons to practice osteopathy The bill defines osteopathy as "a system of practice of the healing arts in all its branches with therapeutic majoring in manipulation" Just what a license to practice osteopathy will permit the licensee to practice is not clear but, as all applicants will be examined in surgery, obstetrics and gynecology, the license conceivably may permit the practice of obstetrics and the performance of all forms of surgery

#### Indiana

*Bill Passed*—H 134 passed the house February 14, proposing, as a condition precedent to the issuance of a license to marry, that each party to a prospective marriage present a physician's certificate that he or she has been given such examination, including a standard serologic test, as may be necessary for the discovery of syphilis and that in the opinion of the physician the party is not infected with syphilis or, if so affected, is not in a communicable stage of that disease

*Bills Introduced*—H 418 proposes that all actions against physicians, dentists or hospitals for malpractice, error, mistake or failure to cure, whether based on contract or tort, must be commenced within two years after the cause of action accrues The bill proposes that a cause of action will be deemed to have accrued on the date of the act or neglect complained of H 477 proposes, among other things, to prohibit the retail sale or distribution of barbituric acid, aminopyrine, cinchophen, dinitrophenol or sulfanilamide except on the written prescription of a licensed physician, dentist or veterinarian H 494 proposes to require every physician, dentist and nurse on or before July 1, 1939, and at least once every twenty-four months thereafter, to submit a sample of his blood to an approved laboratory for a standard serologic test for syphilis If the test indicates infection, the license of such person is to be suspended automatically and remain suspended so long as the disease is in a communicable stage

#### Kansas

*Bills Introduced*—H 330 proposes to repeal existing laws regulating the possession and distribution of narcotic drugs and to enact what appears to be the uniform narcotic drug act H 375 proposes to impose a tax on the gross receipts derived from professional services, amounting to fifteen mills on the dollar

#### Maine

*Bills Introduced*—H 1416 proposes to give to any hospital, not organized for profit and furnishing hospital service or materials to any patient injured by any accident not covered by the workmen's compensation act, a first lien on such proceeds or any accident and liability insurance policy issued by

any insurance company as may be due the patient, either directly or indirectly H 1432 and H 1433 authorize the formation of nonprofit hospital service corporations to enter into contracts with subscribers for the rendering of hospital service to them through hospitals contracting to do so with the corporations in question H 1645 proposes to create a department of professional licensing to exercise all the powers and functions heretofore vested in the secretaries of the various licensing boards of the state, including the medical board, the osteopathic board, the chiropractic board and the dental board H 1706 proposes to require hospitals which are tax exempt or which receive any public funds to permit such osteopaths as are in good standing and are licensed to practice obstetrics and surgery to practice in their confines and to furnish laboratory service to outpatients of osteopaths The present law requires such hospitals to admit osteopaths, subject to the approval of the hospital board to treat their own paying patients and says nothing with respect to the laboratory service which must be furnished to outpatients of osteopaths

#### Maryland

*Bills Introduced*—H 250 proposes to enact a law regulating the manufacture, distribution or advertising of foods, drugs, cosmetics and devices H 325 proposes to authorize the state board of health to establish such minimum standards and qualifications as it may deem necessary for laboratories in the state, except in Baltimore City, which make examinations in connection with the diagnosis and control of human diseases

#### Minnesota

*Bill Introduced*—S 547 proposes to establish a state-wide system for the after-care of patients discharged from county and state tuberculosis sanatoriums

#### Missouri

*Bills Introduced*—S 68 proposes in effect, to permit hospitals to practice medicine through the agency of physicians in their employ H 264 proposes that a licensed physician or the owner or operator of a private sanatorium or hospital shall not be liable in damages for the restraint of any insane person or person of feeble or disordered mind by reason of having in good faith furnished care, treatment or attention to such person

#### Montana

*Bills Introduced*—H 249 proposes to establish a state hospital to be known as the Montana State Infantile Paralysis Sanitarium H 265 proposes to authorize the state superintendent of public instruction to employ a specialist in the field of health and physical education to direct and supervise the organization of a state-wide program of health and physical education for public schools

#### Nebraska

*Bills Introduced*—Bill 392 proposes to condition the annual renewal of a license to practice osteopathy on the presentation of proof that the holder in the preceding year has attended at least two days of the annual 'educational' program as conducted by the Nebraska State Osteopathic Association, or its equivalent Bill 476 proposes a procedure whereby hospitals may be reimbursed by the state for treating indigent persons injured in motor vehicle accidents

#### New Hampshire

*Bill Introduced*—H 327 proposes to create a commission on disability benefits to compile a report on the possibility of protecting individuals unemployed because of sickness or ill health

#### New Jersey

*Bill Enacted*—S 61 has been enacted as Laws 1939 chapter 13 appropriating \$25 000 to the State Department of Health for the purchase and free distribution of antipneumococcus serum for the treatment of persons affected with pneumonia and financially unable to purchase the serum

*Bills Introduced*—A 199 proposes to enact a separate chiropractic practice act and to establish an independent board of chiropractic examiners to examine and license persons to practice chiropractic The bill defines chiropractic as that branch of medi-

cine and surgery which treats with ailments of the foot and leg and includes the diagnosis of the medical, surgical, mechanical manipulative, and electrical treatments of all the ailments of the human foot and leg, excepting amputation of the leg foot or toes, or the use of any anaesthetic other than local, or the treatment of congenital deformities by the use of the knife or radical operations for talipes valgus, or the treatment of varicose veins by injection or surgery " A 200 proposes to authorize a judge of the court of common pleas, after notice and hearing to commit a narcotic addict to any state, county or city institution for the care and treatment of his addiction

#### New Mexico

*Bills Passed*—S 111 passed the senate February 20, proposing to permit the organization of corporations to operate hospital service plans and to provide that such a corporation may be organized by filing a certificate setting forth its name, its object, location and term of existence with the Superintendent of Insurance of the State, who is to endorse thereto his consent and file it in the Office of the State Corporation Commission H 259 passed the House February 22, proposing to make it a misdemeanor, punishable by a fine of from \$100 to \$500, for any person practicing the healing art to fail to specify on any sign or other advertising to the public the particular branch of the healing art which he practices H 51 passed the House January 27, proposing to require the governing authority of every public high school in the State to arrange for instruction in the public high schools concerning the prevention of venereal diseases

#### New York

*Bills Introduced*—S 877 proposes to enact a self-styled New York uniform food drug and cosmetic act to regulate the manufacture, sale or advertising of foods, drugs cosmetics and devices A 1064 proposes to prohibit the practice of radiology except by licensed physicians, dentists, osteopaths and chiropractors subject, however, to the conditions and limitations of their licenses The bill proposes to define radiology as 'diagnosis and/or treatment of diseases by means of exposure to roentgen rays and/or radium' A 1090, to amend the law permitting a court whenever it is relevant to the prosecution or defense of an action to direct any party to the action and the child of any such party and the person involved in the controversy to submit to one or more blood grouping tests, proposes also to permit a court to order such a test wherever it shall be relevant in any proceeding pending in a court of record A 1137 proposes to make it a misdemeanor for any hospital wholly or partly supported by public funds or exempt from taxation to refuse to permit any licensed physician the right to attend treat and prescribe for any patient therein desiring his services

#### North Carolina

*Bill Passed*—S 119, which passed the senate February 23, proposes to require the parent or parents or guardian of any child to have administered to the child between the ages of 6 months and 12 months an immunizing dose of a prophylactic diphtheria agent meeting the standard approved by the United States Public Health Service for such biologic products This duty is also to be imposed on the parent or parents or guardian of any child between the ages of 12 months and 5 years who has not been previously immunized against diphtheria If the parent or parents or guardian of such child are unable to pay for the services of a private physician for the immunization referred to the appropriate county health officer is to administer the treatment

#### North Dakota

*Bills Introduced*—H 267 proposes as a condition precedent to the issue of a license to marry that each party to the proposed marriage present a physician's certificate that he or she has been given such examination, including a standard serologic test as may be necessary for the discovery of syphilis and that in the opinion of the physician the party either is not infected with syphilis or, if infected is not in a stage of the disease which is or may become communicable to the marital partner S 194 proposes that an action may be commenced by the state by any person who has a special interest in the action against any person practicing without a license, any profession requiring a license or certificate or other legal

**authorization** One of the results of the enactment of this bill may well be to permit the issuance of injunctions to restrain the unlicensed practice of medicine. H 281 proposes to authorize counties, either separately or in conjunction with one or more contiguous counties, to establish and maintain full time local health departments. H 388 proposes to impose a tax of 2 per cent of the gross income received from any business, trade, profession or occupation.

### Ohio

**Bills Introduced**—S 181 proposes to organize the organization of corporations not for profit to establish and operate non-profit hospital service plans whereby hospital service may be provided by hospitals with which such corporations have contracted to such of the public as become subscribers to said hospital service plans. H 268, to revise and codify the laws relating to marriage, proposes, among other things, as a condition precedent to the issuance of a license to marry, that each party to a proposed marriage present a physician's certificate that he or she is free from venereal disease, epilepsy, feeble-mindedness and insanity, as nearly as can be determined by thorough examination and by the application of the recognized clinical and laboratory tests of scientific research approved by the State Director of Health.

### Oklahoma

**Bill Passed**—S 92 has passed the senate, proposing to require every physician attending a pregnant woman to take or cause to be taken a sample of her blood at the time of the first examination and to submit that sample to an approved laboratory for a standard serologic test for syphilis.

**Bill Introduced**—H 329 proposes to enact an independent naturopathic practice act and to create a board of naturopathic examiners to examine and license persons to practice naturopathy. The bill defines naturopathy as 'The physiological and mechanical sciences, such as mechanotherapy, articular manipulation, corrective orthopedic gymnastics, neurotherapy, psychotherapy, hydrotherapy and mineral baths, electrotherapy, thermotherapy, phototherapy, chromotherapy, vibrotherapy, thalamotherapy and dietetics, which shall include the use of foods of such biochemical tissue-building products and cell salts as are found in the normal body, and the use of vegetable oils and dehydrated and pulverized fruits, flowers, seeds, barks, roots and vegetables uncombined and in their natural state, and, added to the above definition, will include all methods now in use, as physiotherapy, Indian herb and simple remedy doctoring, physical culture, gynecology [sic], autobiochemistry, colonic-therapy and scientific massage and such methods as are taught in standard schools of Naturopathy.'

### Oregon

**Bills Introduced**—S 353 proposes that "Whenever any person shall receive hospitalization or medical or surgical care on account of any injury and such injured person shall claim damages from the party causing the injury, such hospital or person rendering medical or surgical care shall have a lien upon any sum awarded the injured person in judgment or obtained by a settlement or compromise on the amount due for the reasonable value of such hospitalization or medical or surgical care rendered the injured person." This bill proposes to repeal the existing law which grants a similar lien to hospitals under the circumstances stated. H 403, to amend the workmen's compensation act, proposes to make compensable an occupational disease arising out of and in the course of employment.

**Bill Passed**—H 415 passed the house February 20, proposing a procedure for the reimbursement of hospitals treating indigents injured in motor vehicle accidents.

### South Dakota

**Bills Introduced**—H 247 proposes to require every physician attending a pregnant woman to take or cause to be taken a sample of her blood at the time of the first examination and to submit such sample for standard serologic tests for syphilis to the State Hygienic Laboratory of the State Board of Health or such other laboratories as are approved by the State Board of Health. H 248 proposes to require as a condition precedent to the issuance of a license to marry that both parties to a

proposed marriage present a certificate from a licensed physician that they are either free from syphilis or are not in a stage of the disease whereby it may become communicable, as nearly as can be determined by a thorough physical examination and such standard microscopic and serologic tests as are necessary for the discovery of syphilis.

**Bill Enacted**—H 10, the basic science bill, was approved by the governor February 23. The new law will require all applicants for licenses to practice any form of the healing art, as a condition precedent to examination and licensure by their respective professional boards, to pass examinations in anatomy, chemistry, physiology, pathology and bacteriology to be given by a board of basic science examiners.

### Tennessee

**Bills Introduced**—S 547 and H 739 propose to prohibit the retail sale and distribution of barbitol except on the written prescription of a licensed physician, dentist or veterinarian. H 758 proposes to grant to hospitals, treating persons injured through the negligence of others, liens on all claims, rights of action, judgments, compromises or settlements accruing to the injured persons because of their injuries.

**Bills Passed**—H 835, to supplement the medical practice act, has passed the house and senate, proposing to prescribe a procedure which must be followed in the revocation or suspension of licenses and to confer on the board of medical examiners stated powers with respect to such proceedings. The bill proposes that in such proceedings the accused physician must be given fifteen days' notice of the time set for the hearing and must be given an opportunity to prepare his defense, and is to be heard in person or by counsel, or both. The board is given the power in such proceedings to administer oaths, issue subpoenas and to enforce the attendance and testimony of witnesses. A companion bill, S 619, was introduced in the senate February 4. H 609 passed the house February 22, proposing to require, as a condition precedent to the issuance of a license to marry, that each party to the proposed marriage present a physician's certificate that he or she has submitted to a physical examination, including a Wassermann and/or Kahn blood test, or other similar laboratory blood test, including a darkfield test where indicated, and that in the opinion of the physician the party is free from venereal disease.

### Texas

**Bill Introduced**—S 81 proposes to appropriate \$50,000 to the State Department of Health to assist in the eradication and control of pneumonia in the state.

### Utah

**Bills Introduced**—H 225 proposes to authorize the organization of what the bill denominates health cooperatives to provide medical, dental, hospital and related services to their members. A cooperative may contract with or employ persons qualified to render any of the health services noted to its members. It may also contract for, own or operate such hospital, clinical, medical or dental facilities as it deems necessary. It is to be authorized to secure membership by advertisement, solicitation or any other means. H 198 proposes to raise to \$10 the annual license renewal fee required of physicians and surgeons, osteopaths, chiropractors and dentists.

### Washington

**Bills Passed**—S 159 passed the senate February 21, proposing to make it unlawful for any hospital organized as a charitable institution to refuse to any licensed physician and surgeon the use of facilities therein or the right to attend patients therein, or refuse admittance to any patient for the direct or indirect reason that a particular physician and surgeon contracts to give medical service in consideration of payment of periodic premiums or dues or because of any physician's membership or nonmembership in any society or other lawful organization. H 325 has passed the house and senate, proposing to amend the law approved by the governor February 3 prohibiting the retail sale or distribution of amital, luminal, veronal, barbitol, acid diethylbarbituric or any of their salts, derivatives or compounds except on the prescription of a licensed physician, dentist or veterinarian. H 325

proposes specifically that "It shall be unlawful for any person, firm or corporation to sell, give away, barter, exchange or distribute amytal, luminal, veronal, barbital, acid diethylbarbituric, or any of their salts, derivatives, or compounds of the foregoing substances or any preparation or compound containing any of the foregoing substances, or their salts, derivatives or compounds, or any registered, trade-marked or copyrighted preparation or compound registered in the United States patent office

*containing more than one grain to the avoirdupois or fluid ounce of the above substances'* except under the written prescription of a licensed physician, dentist or veterinarian. Provisions of the law approved February 3 restricting the sale of para-amino benzene sulfonamide, sulfanilamid sulfamidyl, prontosil, prontosil, neo prontosil, edimalin, sulfonamid or any of their salts, derivatives or compounds are not changed by the provisions of H 325

**Bills Introduced**—S 263 proposes to enact a separate sanipractic practice act and to establish a sanipractic physicians examining board to examine and license persons to practice sanipractic. The bill proposes the following definition "Sanipractic is the science and art of applied prophylactic and therapeutic sanitation which enables the physician to direct, advise, prescribe or apply food water, roots herbs, light, heat, exercises active and passive, manipulation, adjusting tissue vital organs and anatomical structure by manual, mechanical or electrical instruments or appliances or other natural agency, to assist nature restore a psychological and physiological interfunction for the purpose of maintaining a normal state of health in mind and body. Above definition copyrighted 1919 for the purpose of protecting a separate and coordinate principle of healing". This bill was reported unfavorably to the senate February 22. S 311 proposes to create a commission to investigate the organization operation and control of hospital associations medical service bureaus and other organizations supplying medical, hospital or surgical care. On the basis of its investigation and study the commission is to make recommendations to the 1941 session of the legislature respecting the regulation and control of persons or organizations engaging in the activities under study. S 315 proposes to enact what it denominates the Washington uniform food drug

and cosmetic act to regulate the manufacture, distribution and advertising of foods, drugs, cosmetics and devices. H 387 proposes to impose the following additional annual license fees on practitioners of the professions and occupations noted: drugless healing \$3, medicine \$5, midwifery \$3 and veterinary medicine \$3.

#### West Virginia

**Bills Introduced**—S 152 proposes that the provisions of the medical practice act "shall not be construed to apply to the practice of Christian Science, provided that the laws, rules, and regulations relating to communicable diseases and sanitary matters are not violated". H 268, to amend the laws authorizing the sexual sterilization of certain socially inadequate inmates of state institutions proposes to authorize the sexual sterilization of any inmate of a state institution afflicted with or suffering from any of the following conditions: (1) mental disease which may have been inherited and is likely to be transmitted to descendants; (2) feeble-mindedness or mental deficiency, in any of its various grades, or (3) perversion or marked departure from normal mentality. The bill also proposes that any person found guilty of a carnal abuse of a female under 16 may, in addition to such other punishment or confinement as may be imposed by court, be subject to sexual sterilization. H 352 proposes to make it unlawful for any person to use the prefix "Doctor" or "Dr" in connection with his name in any letter, business card, advertisement, sign or public display of any nature whatsoever, without affixing thereto suitable words or letters designating the degree which he holds.

#### Wisconsin

**Bills Introduced**—S 142 proposes to direct the board of control to establish a chiropractic ward at the Winnebago state hospital for the insane. A 311, to amend the law requiring applicants for licenses to marry to present physicians' certificates as to freedom from syphilis, proposes (1) that such a certificate must be signed by a physician licensed to practice either in Wisconsin or in the state in which the applicant resides and (2) apparently, to limit to \$3 the fee which a physician can charge for executing the certificate and making the necessary examination.

## WOMAN'S AUXILIARY

### Oregon

The auxiliary to the Oregon State Medical Society held a meeting of the board in Portland Nov 2 1938. Dr Charles E Sears gave an address on 'State Medicine'.

The auxiliary to the Josephine County Medical Society was organized Oct 30 1938 with eight charter members. Mrs Byron G Bailey, Grants Pass, was elected president.

The auxiliary to the Jackson County Medical Society met Oct 19 1938, having as guest the state president, Mrs Otto C Hagmeier, Seaside. The auxiliary will try to help furnish oxygen for patients who cannot afford it.

The November meeting of the auxiliary of the Klamath-Lake County Medical Society was spent making bibs and booties for the Doernbecher Memorial Hospital for Children, Portland.

The auxiliary of the Polk-Yamhill-Marion County Medical Society met November 8. Mr R Ivan Loveall, professor of history at Willamette University, Salem, spoke on 'Conditions in Europe Today'.

### Texas

The auxiliary to the Travis County Medical Society met at the home of the president, Mrs C M Darnall, Austin, October 18. Dr B J Lloyd, director of the Austin and Travis County health unit, was speaker.

The auxiliary to the Wichita Medical Society held a breakfast meeting at the Woman's Forum Club House, Wichita Falls, October 11. Dr C W Monroe of Electra spoke on socialized medicine.

Dr S E Thompson of Kerrville spoke on socialized medicine at a meeting of the auxiliary to the Fifteenth District Medical Society and the society in Texarkana, October 13.

### Utah

The auxiliary to the Salt Lake County Medical Society met at the Lion House Social Center, Salt Lake City, October 17. Mrs Henry Raile, president, presided. Members discussed 'The Doctor of Yesterday,' 'The Intern of Today,' 'The Dilemma,' 'We Might' and 'Doctors' Day'.

The auxiliary to the Carbon County Medical Society sponsored a public meeting held at the Elks Club, Price, recently. Dr Edward L Van Alstyn and Miss Jane West of the public health service discussed community health problems. The officers of the state medical association and of the auxiliary held a joint meeting October 9 at Price with the Carbon County Medical Society and its auxiliary as hosts. Dr L A Stevenson, Salt Lake City, discussed the program for medical legislation and Mr W H Tibballs talked on socialized medicine.

The executive board of the auxiliary to the Utah Medical Association met at Salt Lake City, October 13, with Mrs Walter M Stookey, president, presiding. The members voted to undertake the preparation of a history of the pioneer physicians of Utah.

### Washington

The auxiliary to the Washington State Medical Association cooperated with the association in sponsoring 'Your Health Exposition' held in Seattle in September. Exhibits from the American Medical Association and from local health organizations were shown. The exposition was attended by thousands of persons.

The auxiliary to the Cowlitz County Medical Society met at Longview in September. Dr J W Henderson spoke on legislation and public health at a meeting November 16. The

program included a debate on "Resolved that socialized medicine would provide more adequate care for the public than our present system"

At a recent meeting of the auxiliary to the Pierce County Medical Society, Dr Charles Engeles and Dr W G Cameron spoke on legislative questions affecting the practice of medicine

A meeting of the King County auxiliary was held November 21 in Seattle "The Life of Chevalier Jackson" and "The Horse and Buggy Doctor" were reviewed More than 100 members were present

The auxiliary to the Walla Walla County Medical Society met October 14 at Walla Walla Candidates for the state

legislature presented their views on medical subjects Mrs R E Ahlquist, president of the auxiliary to the Washington State Medical Association, discussed plans for the year's work

At a recent meeting of the auxiliary to the Yakima County Medical Society, Dr Paul Lewis spoke on "The Six Most Common Diseases and Causes of Death" Mrs J C Applewhite of Clarkston, parliamentarian for the State Federation of Women's Clubs, spoke on parliamentary procedure

At a meeting of the auxiliary to the Spokane County Medical Society October 14, Dr McIntyre, president of the society, talked on medical legislation On November 11 'Socialized Medicine' was discussed

## MEDICAL ECONOMIC ABSTRACTS

### CUT RATE EXAMINATIONS

A physician in Dayton, Ohio, has received the following letter from a "transport service bureau" in Detroit

A trucking company has requested us to aid them in obtaining the services of a legally qualified physician in Dayton for the purpose of making medical examination of their drivers They have about five employees to be examined These examinations are made to ascertain the physical fitness of the drivers who operate a motor vehicle on the public highway They have eleven other terminals where examinations have been made or are in the process of being made by physicians such as Toledo and Columbus and the doctors in those cities do the work for \$1 per examination on the form attached hereto which includes urinalysis but does not include blood test Will you kindly advise if you will accept an appointment and if so we will then send you full instructions and supplies also direct the employees to call at your office for these examinations In event you accept the appointment any other trucking company having employees to be examined in Dayton will be referred to you Will you kindly give us an immediate reply as they are desirous of having these examinations made at once

The copy of the Medical Examiner's Report which is attached to the letter calls for an examination of visual acuity, with and without glasses, for each eye, and an isolation and combination test for color blindness The physician is also asked to state the degree of impairment of hearing on a percentage basis for each ear In addition, he is asked to answer the question "Do you find evidence of *past* or *present* disease or impairment of the following" (*italics in original*)

- (a) Eyes 1 Right eye?  
2 Left eye?
  - (b) Hearing 1 Right ear?  
2 Left ear?
  - (c) Nose or throat?
  - (d) Teeth and gums?
  - (e) Skin thyroids glands?
  - (f) Brain or nervous system?
  - (g) Lungs or pleurae?
  - (h) Pulse rate 1 Before exercise?  
2 After exercise?
  - (i) Heart (Examine before and after 30 hops on one foot)  
1 Is there a murmur?  
2 Is there dyspnea or other evidence of heart failure?
  - (j) Blood pressure 1 Systolic?  
2 Diastolic?
  - (k) Stomach or abdominal organs?
  - (l) Rupture?
  - (m) Piles?
  - (n) Maimed or deformed?
  - (o) Any restriction in motion of any joint
  - (p) Syphilis?
  - (q) Venereal disease?
  - (r) Varicose veins or ulcers?
  - (s) Rheumatism?
  - (t) Any chronic or recurrent disease or deformity not included above?
- Urinalysis Reaction? Specific gravity? Albumin? Sugar?

The physicians are then instructed, with regard to any of these questions, "When answered 'Yes' give details"

It may be assumed that the "transport service bureau" expects accurate and complete information on all the items listed If such an examination is actually made conscientiously by a physician who is willing to defend his results, it would require from one to more than two hours of time and possibly a consultation with or referral to some specialists for confirmation The amount of laboratory work would, of course, vary with different persons, but a minimum must be performed including a serum test for syphilis

For all this the physician is to receive *one dollar* By what intellectual legerdemain can it be concluded that the physician who undertakes such examinations will receive a fair fee for his services? And again, is it possible for any one to deliver a dependable service of the type requested for the price that is authorized?

### MORBIDITY RISES UNDER BRITISH INSURANCE

"The National Health Insurance Act was designed principally as an instrument to improve the standard of curative medicine in general practice by replacing the old club system of contract practice," said Dr A B Walker, regional medical officer, Department of Health for Scotland, in an address at the 1938 health congress at Portsmouth, published in the *Journal of the Royal Sanitary Institute* (59 511 [Jan] 1939)

It was reasonable to hope that this act together with the improved environmental services by providing early and effective treatment would have some effect, not only in diminishing the amount and duration of disabling illness, but also an important preventive element Yet, whilst sickness insurance on a national scale is a social service of proved value, it has not had these effects Morbidity data available during the past few years show that incapacitating illness has tended to rise and with yearly fluctuations remains today at a new high level This persistence of incapacitating illness amongst the insured population at a high general level, in spite of advances in preventive and curative medicine is indicated in the successive Annual Reports on Incapacitating Sickness in the Insured Population, published by the Department of Health for Scotland It is a fact which deserves the serious consideration of all interested in the public welfare"

### UTAH STATE MEDICAL ASSOCIATION PREPAYMENT PLAN

The House of Delegates of the Utah State Medical Association has endorsed a plan of combined hospital insurance and cash indemnity for a limited amount of medical care The hospital plan follows the general lines of existing plans except that anesthesia and laboratory and x-ray services are provided for on a cash indemnity basis instead of being included in hospital care The annual premium for the hospital plan is \$10 for an individual, \$18 when one dependent is included and \$24 for an entire family regardless of size

Only those who are covered by the hospital insurance plan are included in the cash indemnity plan for general medical care The additional premiums are exactly the same as for hospital care making \$21.60 annually for an individual \$36 for an additional dependent and \$48 for a family for both hospital and medical care The amounts to be reimbursed to the insured for various medical services are set forth in a schedule, and surgical services are limited to one major and one minor operation per member in a single year

Enrolment is confined to employed persons and to groups which may be either employees of a common employer or members of church and fraternal groups and their dependents agreeing to collect the necessary membership fees by assessment or subscription, remitting through a designated agent

## Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES NEW HOSPITALS EDUCATION AND PUBLIC HEALTH)

### ALABAMA

**Society News**—A joint meeting of the southwestern and northwestern divisions of the state medical association was recently addressed in Tuscaloosa, among others, by Drs Gerald H Teasley, Athens, on 'Nitrous Oxide-Oxygen in Rural Obstetrics', Kellie N Joseph, Birmingham, 'Diagnosis and Treatment of Pleural Effusions', William M Bland, Tuscaloosa 'Preoperative Diagnosis of Gallbladder Disease Made Possible Through Laboratory Analysis in Conjunction with Fluoroscopic Examination of the Gallbladder and Duodenum', Benjamin T Beasley, Atlanta Ga, "Surgical Management of Damaged Genital Supports in the Female," and William G Harrison Jr, Birmingham, "Therapy of Heart Disease" The luncheon meeting was addressed by Richard C Foster, DCL, president of the University of Alabama, and Drs Stuart Graves, University, William D Partlow, Tuscaloosa, and Seale Harris, Birmingham

### ARKANSAS

**District Meeting**—The Fifth Councilor District Medical Society met at El Dorado January 11 The speakers included Drs Richard B DeLee and Harold G F Edwards, both of Shreveport, La, on "Bronchial Asthma" and 'Carcinoma' respectively

**State Health Board Election**—Dr. William Webber Kelly, Green Bay, was elected president of the state board of health at a meeting in Madison January 6. Dr. Stephen Cahana, Milwaukee, was made vice president and Dr. Cornelius A. Harper, Madison, remains secretary and state health officer.

**Bardeen Memorial Lecture**—Dr. Stephen W. Ranson, Chicago, delivered the Bardeen Memorial Lecture at the University of Wisconsin Medical School, Madison, February 28. His subject was 'The Hypothalamus'. Dr. Ranson is director of the Neurological Research Institute, Northwestern University Medical School, Chicago.

**Society News**—At the annual meeting of the Milwaukee Society of Clinical Surgery January 24 the speakers were Drs. William J. Carson, retiring president, on 'The Science of Surgery'; Karl F. Schlaepfer, incoming president, 'Nupercaine Spinal Anesthesia in General Surgery'; and Lucius W. Hipke, 'Gastrectomy—Results in Ten Consecutive Cases Ten Years After Operation'.

**University Develops Cancer Research Facilities**—Research on cancer at the University of Wisconsin, Madison, is to be centralized in a new building now in process of construction. Funds amounting to about \$240,000 have been provided for the building by a special bequest, by a contribution from the Wisconsin Alumni Research Foundation and a PWA grant of \$108,000. It will be 102 feet long and 50 feet wide and will be connected with the Memorial Service Institutes of the university and Wisconsin General Hospital. Two floors will be devoted to biologic research, one to x-ray diagnosis and the first floor to radiologic research and treatment. The new building cannot offer space to all the university's work on cancer, which is being pursued in zoology, plant pathology, agricultural chemistry, physics chemistry and various departments of the medical school but it will have conference rooms and will serve as a clearing house to unify the varied activities according to the *Wisconsin Medical Journal*. In the Wisconsin General Hospital cancer patients from all parts of the state are received making all types of the disease accessible to research workers. The entire development is being directed by a graduate school committee consisting of Drs. William S. Middleton, dean of the medical school, chairman; Edwin B. Fred, Ph.D., dean of the graduate school; and Michael F. Guyer, Ph.D., professor of zoology. Walter J. Meek, Ph.D., professor of physiology and associate dean of the medical school, is chairman of the building committee.

## GENERAL

**Society News**—At the annual meeting of the Federation of State Medical Boards of the United States in Chicago February 14 Dr. John R. Neal, Springfield, Ill., was made president elect and Dr. Roy B. Harrison, New Orleans, became president. Dr. Frank M. Fuller, Keokuk, Iowa, was elected vice president and Dr. Walter L. Biering, Des Moines, Iowa, reelected secretary.

**Examinations in Anesthesiology**—Applications for the examination to be given April 8 by the American Board of Anesthesiology are now closed. Applications for the oral examination in St. Louis in May will be received until March 13. The next written examination will be held in various places September 9. The oral examination, part II, will be held in Philadelphia October 14-15. Application for this examination must be made by July 11 to the secretary, Dr. Paul M. Wood, 745 Fifth Avenue, New York.

**Van Meter Prize Award**—The American Association for the Study of Goiter again offers the Van Meter Prize Award of \$300 and two honorable mentions for the best essays submitted concerning original work on problems related to the thyroid gland. The award will be made at the annual meeting of the association in Cincinnati May 22-24, provided essays of sufficient merit are submitted. The essays may cover either clinical or research investigations should not exceed 3,000

words in length, must be presented in English and must be typewritten, double spaced. A copy must reach the corresponding secretary, Dr W Blair Mosser, 133 Biddle Street, Kane, Pa., not later than April 15.

**Grants for Research on Sex Problems**—Requests for aid from the National Research Council's committee for research in problems of sex and reproduction must be received before April 1, it is announced. In addition to a statement of the research to be undertaken, the committee desires information about the proposed method of attack, the auspices of investigation and the uses to be made of the sum requested. Preference will be given to proposals for the study of neurologic, psychobiologic and behavioral problems. Requests may be addressed to the chairman of the committee, Robert M Yerkes, Ph D, Yale University School of Medicine, New Haven, Conn.

### LATIN AMERICA

**Mexican Laboratory Named for U S Entomologist**—The National School of Biological Sciences of Mexico recently opened a new laboratory of entomology, which is named in honor of Dr Leland O Howard, chief of the U S Bureau of Entomology from 1894 to 1927 and principal entomologist of the U S Department of Agriculture from 1927 to 1931, when he retired. Dr Howard was unable to be present at the ceremonies. Ambassador Josephus Daniels made an address in which he outlined Dr Howard's career.

**International Meetings This Year**—The Pan American Sanitary Bureau has issued a list of international meetings to be held in the Americas this year, including the following in Latin America:

Second Pan American Neuropsychiatric Week Lima Peru March 20 28  
Fourth Latin American Congress of Odontology Montevideo March 12 19 (postponed from December 1938)  
Eighth Pan American Child Congress San Jose Costa Rica August 28 to September 4  
Intergovernmental conference of American countries on rural hygiene Mexico City toward the end of 1939 (postponed from Nov. 10 1938)

### FOREIGN

**Society News**—The British College of Obstetricians and Gynaecologists will now be known as the Royal College of Obstetricians and Gynaecologists.—The fourth International Congress of Comparative Pathology will be held in Rome May 14-20 with sections devoted to human, veterinary and plant pathology.

**Red Cross Health Committee**—The Advisory Health Committee of the League of Red Cross Societies held its second meeting at the headquarters of the league in Paris last October. The countries represented were Colombia, France, Germany, Great Britain, Guatemala, Italy, Japan, Latvia, Siam, Sweden, Yugoslavia and the United States. Dr Hugh S Cumming, former surgeon general of the U S Public Health Service, represented the United States. The principal subject discussed was the health of infants and preschool children in rural areas in the various countries.

## Government Services

### Annual Report of Food and Drug Administration

During the fiscal year ended June 30, 1938, the last complete year of enforcement for the Food and Drugs Act of 1906, the Food and Drug Administration of the Department of Agriculture sampled or inspected 68,125 shipments in interstate commerce and imports for possible violations of the law. On interstate samples 1,992 seizures were made and 726 prosecutions were begun.

Two major tragedies attributable to unsafe drugs occurred during the year, the deaths of more than 100 persons caused by "Elixir of Sulfanilamide" and twelve deaths from an alleged cancer serum contaminated with tetanus toxin. In a drive to remove the elixir from the market, the administration's agents accounted for 1,905 pints, 9 fluid ounces, which was 99.2 per cent of the entire amount manufactured. The data show that 93 pints, 6 fluid ounces reached consumers and about half of that amount was consumed. In the investigation of the cancer serum deaths the administration examined 111 10 cc ampules. Forty-one of these bore the number of a lot which appeared to be the only one containing tetanus toxin, of these eighteen contained the toxin.

The administration made an extensive survey of rubber and membrane prophylactics against venereal disease and 181 con-

signments of these products labeled as useful in prevention of disease were seized when examination showed them to be defective. As a result, many producers withdrew stocks from the market and made drastic changes in manufacturing processes.

False claims on medicines accounted for criminal prosecutions against forty-five defendants and 117 seizures of the products of eighty-six shippers. Chemicals and preparations purporting to comply with the standards of the U S Pharmacopeia gave rise to forty-three seizures and prosecutions against thirteen manufacturers, the administration analyzed 2,072 samples, exclusive of ether. Of 2,916 cans of ether tested, 111 failed to meet the pharmacopeial standard. Criminal action was brought against one manufacturer for glandular products that did not meet the standard.

Totals of 1,564 samples of National Formulary chemicals and twenty-five glandular products were examined, resulting in criminal action against seven manufacturers.

Unofficial chemicals, including glandular products to the number of 2,757, the output of about 500 producers, were examined. Criminal prosecutions were instituted against nine manufacturers of unofficial chemicals and preparations and against three manufacturers of unofficial glandular products.

The administration's food activities included 297 seizures of fruits and vegetables for excessive spray residues, an increase over the previous year, due largely to crop increases, the report stated. In one state, however, certain growers sprayed their apples much later than was recommended and then refused to incur the cost of washing. As a result sixty-nine seizures were made of shipments from this state alone.

The problem of metallic contamination continued to be important. Two hundred and twenty-nine lots of imported sardines were examined and eighteen were refused entry because of the presence of excessive lead. A special campaign has been carried on with respect to maple products in an effort to induce producers to cease using lead bearing equipment and utensils. Examination of 300 samples resulted in twenty-two seizures. Ninety-five import lots were examined, of which forty one, amounting to 2,600,000 pounds, were refused entry. Although these operations were intended for the immediate protection of the consumer, they have had the effect of hastening fundamental corrections, the administration reported.

As a result of the "Elixir of Sulfanilamide" episode, attention was directed to the danger of use of diethylene glycol in flavoring extracts. In the course of a campaign 103 consignments of solvents and 104 shipments of flavors containing them were seized. Within a few months stocks of these solvents for food use and all food products containing them disappeared from the market.

More than 254,000 cans of cream for butter making were examined by state and federal forces, of which 6,957 were condemned. The salmon pack for 1937, amounting to about 7½ million cases, required no action, the report said. Twenty-seven lots of imported tuna, totaling 160,000 pounds, were detained, some because of lead and some because of decomposition. Of domestic tuna seven shipments were seized and one prosecution was instituted.

An important project of the year was a survey of the confectionery industry for the purpose of regulating certain manufacturers who rework and redistribute unfit stocks. Sanitary conditions were found to be deplorable in some factories; raw materials carelessly stored and objectionable, returned material was being reworked by some firms for cheap sale.

Of 379 plants examined, the majority were scrupulously clean, but seventy-eight small consignments, the product of thirty-eight manufacturers, were seized. Prosecution has already been recommended against five for shipping filthy candy and actions against others are in preparation.

Fines assessed by federal courts in food and drug cases under the statute ranged from as low as \$4 to a maximum actually paid of \$3,000.

The new Food, Drug and Cosmetic Act becomes completely effective next June 25. Sections designed to protect the consumer against dangerous drugs and cosmetics went into effect immediately on approval by the President June 25, 1938.

### CORRECTION

**Foreign Physicians Qualify for Licenses**—Under New York news February 25, page 755, THE JOURNAL stated that 622 of 1,063 foreign physicians who took the state medical examinations in January were successful. According to the New York Times this figure appeared for the results of the state medical examinations for 1937-1938.

## Foreign Letters

### LONDON

(From Our Regular Correspondent)

Feb 4, 1939

#### Traumatic Rupture of the Common Bile Duct

Uncomplicated rupture of the common bile duct due to injury must be a very rare condition. Mr A. C. Lysaght observed at the Cardiff Royal Infirmary the following case, which he has reported in the *British Journal of Surgery*. A man aged 32, a steel erector, was struck in the back by a steel rafter weighing about 3 hundredweight, which was swinging on a crane, and was thrown forward on his stomach against a pile of steel girders. He felt excruciating pain and was taken to the hospital in an ambulance. On arrival, about an hour after the accident, he vomited undigested food, and he continued to do so. He was in severe abdominal pain, the legs were flexed, and there was boardlike rigidity of the abdominal muscles. There was bruising of the lower part of the back but none of the abdomen. The abdomen was exquisitely tender all over but especially in the right hypochondriac region. There was no dulness in the flanks, and dulness of the liver was present. The temperature was 96 F, the pulse rate 90 and the respiratory rate 18. Rupture of a viscus, probably the small intestine, was diagnosed.

The abdomen was opened, with the patient under spinal anesthesia supplemented by gas and oxygen, by a long paramedian incision to the right. The peritoneal cavity was full of bile-stained fluid. The small intestine showed no injury. The incision was enlarged upward for examination of the biliary organs. A small tear was found at the first and second parts of the duodenum, which was repaired. Morrison's pouch was full of bile, which reaccumulated after emptying. This was found to exude from a minute opening in the free border of the foramen of Winslow. When this was enlarged it was found that the common bile duct was completely severed. The lower end of the duct could not be found, it apparently had retracted. Closure of the upper end of the common bile duct and anastomosis of the gallbladder with the stomach was performed. The abdomen was closed with drainage, and recovery was uninterrupted.

#### Sir Robert Philip

Sir Robert Philip, professor of tuberculosis in the University of Edinburgh and until recently chairman of the National Association for the Prevention of Tuberculosis, has died at the age of 81. He was the first to evolve a system for the open air treatment of tuberculosis in all stages from the teachings of Bodington, Brehmer and other pioneers. The disease had long been regarded as a deadly inheritance in certain families and under the name decline was a favorite cause of death of sentimental Victorian novelists. The treatment consisted in keeping the patient in one room with freedom from drafts, which were thought to be injurious. Then came Koch's discovery of the bacillus of tuberculosis. In 1888 Philip published in the *British Medical Journal* a paper entitled 'A Contribution Toward the Etiology of Phthisis' in which he argued that, although the bacillus was the cause of the disease, clinicians had not a rational conception of the cause of death. He experimented on animals with sterilized tuberculous sputum, which proved to be very toxic. He was the first in this country to realize the importance of preventing infection to investigate the conditions under which the families of the patients lived and to teach them how to avoid infection. In 1887 he founded the first tuberculosis dispensary in the world, holding that for every patient with diagnosed open tuberculosis there

must be many infected contacts, who should be examined. Three years later Calmette founded a similar dispensary at Lille. Philip was the first in this country to realize the need for various coordinated institutions, the sanatorium, the farm colony, the open air school and the hospital for patients with advanced tuberculosis. The system became known as "the Edinburgh system." In 1890 he was awarded the Alvarenga prize of the College of Physicians of Philadelphia for an essay on pulmonary tuberculosis. In 1908 he attended the International Congress at Washington. Two years later he was asked what might be expected from a ten year program of operations proposed by a conference in Albany, N. Y. He wired in reply "Prosecute great program proposed, watch child as potential tuberculosis seedling, correct faulty compulsory environment and expect 40 per cent reduction by 1920 and practical disappearance within a generation and a half." In 1928 he received the Trudeau medal of the American Tuberculosis Association, given annually for the most meritorious contribution to the knowledge of tuberculosis.

#### A Symposium on Pulmonary Embolism

Reference was made in a previous letter to the experimental study of the etiology and mechanism of pulmonary embolism by Prof. Maurice Villaret and his co-workers. They found that the size of the embolus is of far less importance in giving rise to sudden death than hitherto believed. Complete obstruction of a large pulmonary artery by a foreign body will not be followed by an immediately fatal result in animals, whereas the intravenous injection of finely pulverized pumice stone, 10 cc per kilogram of the animal's weight, causes extensive and almost invariably fatal embolism. It appears that sudden death following occlusion of a small branch of the pulmonary artery is the result of a reflex set up by irritation of the vessel wall, which acts first on the respiratory and then on the cardiac centers.

At the November 30 meeting of the Société médicale des hôpitaux of Paris, pulmonary embolism in its experimental and clinical aspects was the subject of three papers. In the first, Prof. Villaret and his co-workers, after a brief summary of their experimental work, stated that recent studies by Leriche, Fontaine and Friedmann corroborated the observation that a neurovegetative reflex plays a very important part in embolism. Other investigators here had also confirmed the experimental work of Villaret and his associates. At present an effort is being made to determine whether there is a difference physiologically between the fatal reflexes which have their origin in the arterial zones and those which have their origin in the capillary zones. As to the mechanism of sudden death after embolism, it is not uniform, a fact which corresponds with the variation of the clinical pictures. With massive embolism, the mechanical obstruction of the circulation must be regarded as constituting the essential factor, but the factor of the neurovegetative reflex appears important to explain smaller embolisms.

#### PREVENTION OF EMBOLISM

The prevention of embolism presents less of a problem experimentally than the treatment. Brocq has shown that embolism can be prevented in rabbits by section of the vagus or of the sympathetic and in dogs by administration of atropine, ephedrine and sodium bicarbonate. Lesions such as congestion, hemorrhage or edema, so commonly observed in patients with pulmonary embolism, have been reproduced in animals by Delarue by various operations on the trunk of the vagus or sympathetic and on the cervical ganglions of the

### Prof Albert Fraenkel Is Dead

Albert Fraenkel, whose name is indivisibly linked with strophanthin therapy, died in Heidelberg Dec 22 1938, aged 74. He was especially influenced during his student days at Munich by the physiologist Voit and later at Strasbourg by Recklinghausen and Kussmaul. On account of a pulmonary disorder Fraenkel spent much time in sanatoriums. He thus came to enter practice at Badenweiler, a health resort in the Black Forest. Years later, although he had changed his place of residence, he continued to be known as Fraenkel of Badenweiler. In 1906 he moved to Strasbourg and there laid the foundations of that intravenous strophanthin therapy which was his principal contribution to science. He founded after the war a middle class sanatorium known as Speyerershof, at Heidelberg. This model institution fulfilled a great need of the most worthy class of the German population, namely educated persons in modest circumstances. Here Fraenkel found the opportunity to test the intravenous use of strophanthin with a large number of patients. He established graduate courses at the Speyerershof, and his methods thus came to attain wide recognition in Germany. Later he made his work known abroad by lectures in Anglo-Saxon countries.

Fraenkel emphasized the social significance of medical activity. As he repeatedly said, the social milieu was to him the most telling factor in his consideration of patients. The Rohrbach hospital in Heidelberg a well equipped sanatorium, was his creation. He was a kindly, well balanced person and an excellent physician of the highest scientific rank, one of those figures who contributed so richly to that international prestige of the German physician which endured for so many decades.

### ITALY

(From Our Regular Correspondent)

Jan 22 1939

#### Congress of Internal Medicine

The Societa Italiana di Medicina Interna recently held its annual meeting at Rome. Professor Maragliano discussed preventive medicine with special reference to immunization. An early diagnosis can be made from the history of the patient and by a careful clinical examination. It is not necessary to wait for the development of precise clinical symptoms.

#### MYOPATHIES

Professors Meldolesi of Rome Siedel of Munich and Putti of Bologna were official speakers on primary myopathies. They said that because the muscular pigment myoglobin is greatly reduced in primary myopathies the muscles look like pieces of fish. Knowledge of the nature and function of myoglobin has widened by the study of primary myopathy. Myoglobin is similar to hemoglobin. It binds bimolecular oxygen in the venous blood and induces an intramuscular storage of oxygen for the intracellular respiration of muscular tissues. It is formed in the muscular fibers from a factor which is a derivative of food proteins. The decrease in myoglobin in the muscles alters the metabolism of glucides, creatinine bodies, adenylyrophosphoric acid and the derivatives of the last in the muscle. Consequently there is little utilization of these substances when administered to the patient. Primary myopathy is an organic hereditary disease. Endocrine and pancreatic digestive alterations are frequent. American physicians report curative results from aminoacetic acid.

Professors Siedel and Meldolesi spoke on the chemical properties of myobilin, which is a bile pigment. In the primary myopathies there is destruction of myoglobin with consequent formation of myobilin and increased elimination of bilirubinoid substances in the urine, which gives a positive fluorescent reaction. The elimination of fluorescent substances through the

urine in some cases is 300 times as much as normal. Stereobilin, urobilin and myobilin are identifiable in the urine.

Professor Putti reported satisfactory results from myototomy or progressive functional correction and in twelve cases of primary myopathy. The treatment was followed by physical and reeducational exercises. The results two years after treatment are satisfactory.

#### THE MENOPAUSE

Professor Sebattini of Genoa University was speaker for the second official topic, the menopause. Whether the climacteric and the stopping of ovulation are due primarily to senile involution of the ovary and secondarily to a loss of the maturing functions of the structure from absence of hypophysial hormones in the aged, or the reverse, is still unknown. There is a tendency, however, to believe that the phenomena depend primarily on the ovary. The pathologic disturbances in the climacteric are due to either increased or diminished function of various endocrine glands. The intensity of the sympathetic and endocrine climacteric disorders depend on the constitution. Treatment with estrogenic substance attenuates the disturbances. The physiology of ovulation and menstruation simulates the constant movement of an uninterrupted chain. According to the speaker a true climacteric age in man does not exist. The phrase means either early senility or nervous exhaustion from syphilis, alcoholism or latent myocarditis.

#### ALTERATIONS IN ABDOMINAL ORGANS

The third official topic, associated syndromes of organs at the upper part of the abdomen, was discussed in common with the Societa di Chirurgia, which held its meeting in Rome at this time. Professor Antognetti of Rome concluded that pathologic alterations of a given organ induce simultaneous changes in other structures which are in functional correlation with the involved organ. The physiologic relations of the upper abdominal organs can be considered from the (1) embryologic, (2) vascular and lymphatic, (3) humoral, (4) reflex nervous and nervous and (5) functional synergic correlations.

Professor Pende emphasized the importance of studying associated syndromes of organs of the upper part of the abdomen from the angle of functional correlations of the organs, especially the transverse colon, duodenum and jejunum, stomach, liver, cholecystic and extrahepatic bile ducts, kidneys, adrenals and celiac plexus, including the two vagi and splanchnic nerves and the epigastric segment of the aorta. The fulcrum of physiopathologic correlations of the structures is the balance of insulin and epinephrine secretions, which maintain the regulating neurochemism of the structures. The speaker differentiated the syndromes in seven different nosographic categories as they give predominant symptoms of (1) anemia and dysemia, (2) disturbances of the digestive tract, (3) metabolic and lithiasic disorders, (4) hemodynamic diseases, (5) excretory disorders, (6) dysfunction of the organic powers of defense and (7) neurocenesiopathia.

## Marriages

JAMES LUCIUS DAVIS, Thacker Mines, W. Va., to Miss Katherine Longcor of Greendell, N. J. Nov. 19 1938.

MARION HENRY BERTLING to Mrs. Eleanor Rice Baker, both of Rock Creek, Ohio, at Cortland January 28.

WILLIAM FREDRIC DELP to Miss Dorothy Elizabeth Wallner, both of Pulaski, Va., Nov. 15, 1938.

DAVID GALE DUNCAN, Huntington, Ore., to Miss Miriam Puspanen of Portland January 7.

BEATRICE TOMBLIN to Mr. Henry Gravi, both of Los Angeles at Riverside, Calif., Dec. 31, 1938.

R. FORD RATLIFF, Lucedale, Miss., to Mrs. Nanmie Walker Ratliff of Vancleave January 25.

## Deaths

**John Douglas** ☉ New York, Columbia University College of Physicians and Surgeons, New York, 1898, clinical professor of surgery, New York University College of Medicine, member of the American Surgical Association, fellow of the American College of Surgeons, in 1917 chairman of the surgical section of the New York Academy of Medicine, past president of the New York Surgical Society and the Medical Society of the County of New York, served at various times on the staffs of St Luke's Hospital, Bellevue Hospital, Knickerbocker Hospital, General Memorial and Harlem Eye and Ear Hospital, on the medical draft board during the World War, author of numerous papers and reports on surgical subjects, aged 63, died, Dec 5, 1938, of heart disease

**James Wallace Esler** ☉ Washington, D C, University of Pennsylvania School of Medicine, Philadelphia, 1920, professor of clinical cardiology, Georgetown University School of Medicine formerly secretary of the Washington Heart Association, aged 44, on the staffs of the Garfield Memorial Hospital, Georgetown University Hospital, Central Dispensary and Emergency Hospital, where he died, Dec 15, 1938, of carcinoma of the stomach

**Wrey Gilmor Farwell** ☉ Medical Inspector, Commander, U S Navy, retired, Fort Lauderdale, Fla, University of Pennsylvania Department of Medicine, Philadelphia, 1904, fellow of the American College of Surgeons, served during the World War, entered the navy in 1904 and retired in 1925 for incapacity resulting from an incident of the service, aged 55, died in November 1938 of chronic myocarditis and coronary occlusion

**Andrew S Gregg**, Fayetteville, Ark, St Louis Medical College, 1881, member of the Arkansas Medical Society, past president of the Arkansas State Board of Health, past president of the Washington County Medical Society, health officer, fellow of the American College of Surgeons, on the staff of the Fayetteville City Hospital, aged 81, died, Nov 21, 1938, of coronary thrombosis

**John Penny Kaster** ☉ Topeka, Kan, Rush Medical College, Chicago, 1881, fellow of the American College of Surgeons, chief surgeon, Atchison, Topeka and Santa Fe Railway Company and Hospital Association, aged 81, died, Dec 13, 1938, in a hospital at Wichita, of arteriosclerosis and myocarditis with bundle branch block

**John Punton**, Kansas City, Mo, Miami Medical College, Cincinnati, 1883, member of the Missouri State Medical Association, at one time trustee and professor of nervous diseases, University Medical College of Kansas City, aged 85, died, Dec 3, 1938, of coronary thrombosis and hypostatic pneumonia

**Benjamin Franklin Coe** ☉ Indiana, Pa, College of Physicians and Surgeons, Baltimore, 1895, fellow of the American College of Surgeons, member of the Radiological Society of North America, member and president of the staff of the Indiana Hospital, aged 66, died, Nov 15, 1938, of heart disease

**I Oto Schobl**, Manila, P I, Universita Karlova Fakulta Lekarska Praha, 1904, at one time chief, division of biology, Bureau of Science, formerly associate professor of pathology and bacteriology, Temple University School of Medicine, Philadelphia, aged 61, died, Oct 13, 1938, in Tokyo, Japan

**Lewis Stuart Johnston**, San Antonio, Texas, Dallas Medical College, 1901, served during the World War, at one time acting assistant surgeon, U S Public Health Service, aged 63, died Dec 8, 1938 in El Paso, of sarcoma of the mesentery and pulmonary embolus following operation

**Irving Coburn MacDonald** ☉ Minneapolis, University of Minnesota College of Medicine and Surgery, Minneapolis, 1902, aged 64 on the staff of St Barnabas Hospital, where he died, Dec 5, 1938, of cerebral embolism, cerebral hemorrhage and coronary thrombosis

**Edward Bowe** ☉ Jacksonville, Ill, Rush Medical College, Chicago 1897, on the staffs of the Passavant Memorial Hospital and Our Savior's Hospital, former president and secretary of the Morgan County Medical Society, aged 65, died, Dec 16, 1938, of myocarditis

**Max Baruch** ☉ New York, Albert-Ludwigs-Universität Medizinische Fakultät, Freiburg, Baden Germany, 1909, on the staff of the Central and Neurological Hospital, aged 55, died, Dec 13, 1938, of coronary thrombosis

**Edwin Bruce McDaniell**, Cedar Rapids, Iowa, Rush Medical College, Chicago, 1900, veteran of the Spanish-American War, for many years a medical missionary, aged 65, died Nov 2 1938, in Los Angeles

**John William Bowler** ☉ Hanover, N H, Dartmouth Medical School, Hanover, 1906, for many years professor of physical education at Dartmouth College, aged 73, died, Dec 27, 1938, of pneumonia

**Hunter Boyd Spencer**, Lynchburg, Va, University College of Medicine, Richmond, 1907, member of the Medical Society of Virginia and the American Roentgen Ray Society, aged 55, died, Nov 12, 1938

**Robert White Barton**, San Angelo, Texas, College of Physicians and Surgeons, Baltimore, 1884, aged 78, died, Dec 20, 1938, in the Shannon West Texas Memorial Hospital of chronic myocarditis

**Walter C Sims**, Richland, Ga, Atlanta Medical College, 1898, member of the Medical Association of Georgia, aged 66, died, Nov 20, 1938, of peritonitis and injuries received in an automobile accident

**De Witt C Greene**, Buffalo, University of Buffalo School of Medicine, 1883, member of the Medical Society of the State of New York, aged 81, died, Nov 25, 1938, of myocarditis and arteriosclerosis

**Joseph Conrad Pietroski**, Cicero, Ill, Chicago College of Medicine and Surgery, 1916, aged 49, died, Dec 24, 1938, in St Mary of Nazareth Hospital, Chicago, of coronary thrombosis

**Joseph Stannard Boynton**, Santa Rosa, Calif, University of Vermont College of Medicine, Burlington, 1884, aged 75, died, Nov 11, 1938, of arteriosclerosis and chronic myocarditis

**Lewis N Klove**, Minneapolis, University of Minnesota College of Medicine and Surgery, Minneapolis, 1903, aged 66, died, Nov 9, 1938, of hypertension and cerebral hemorrhage

**Oscar Barksdale** ☉ West Memphis, Ark, University of Tennessee College of Medicine, Memphis, 1914, served during the World War, aged 55, died, Dec 18, 1938, of myocarditis

**John Charles Phillips**, Wenham, Mass, Harvard University Medical School, Boston 1904, served during the World War, aged 62, died in November 1938 of heart disease

**Robert P Dalton**, Cape Girardeau, Mo, Barnes Medical College, St Louis, 1904, formerly member of the city board of health, aged 71, died, Dec 18, 1938, of myocarditis

**Homer Isaac Keeney**, San Francisco, Jefferson Medical College of Philadelphia, 1901, served during the World War, aged 62, died, Nov 21, 1938, of coronary occlusion

**Adolph Fallor** ☉ Chicago, Chicago Medical School, 1918, on the associate staff of the Evangelical Hospital, aged 61, died, Dec 3, 1938, of bronchopneumonia

**Hiram Milton Presler**, San Diego, Calif, Eclectic Medical Institute, Cincinnati, 1894, aged 73, died, Nov 27, 1938, of hypertension and coronary occlusion

**Francis John Vincent Marx** ☉ Westbury, N Y, University of Buffalo School of Medicine, 1923, aged 37, died in November 1938 in Phoenix, Ariz

**Charles Wesley Reed** ☉ Irwin, Pa, University of Kansas School of Medicine, Kansas City, 1932, aged 32, died, Nov 23, 1938, in a hospital at Tulsa, Okla

**Thomas Calvin Kelly**, Sidon, Miss, Medical College of Alabama, Mobile, 1904, aged 63, died, Dec 11, 1938, of hypertension and cerebral hemorrhage

**John Charles Quitmeyer**, Chicago, Chicago College of Medicine and Surgery, 1915, aged 48, was killed Dec 2, 1938, when he was struck by a truck

**Aaron Denenholz**, Brooklyn, New York University Medical College, 1897, on the staff of the Manhattan State Hospital, aged 63, died, Dec 1, 1938

**William Hall Richardson**, Milton Ore, St Louis University School of Medicine, 1905, aged 59, died in November 1938 of bronchopneumonia

**Charles H Griswold**, Modesto, Calif, Chicago Homeopathic Medical College, 1887, aged 77, died, Nov 27, 1938 of carcinoma of the pancreas

**John Richard Lyon**, Mount Pleasant, Ohio, Ohio Medical University, Columbus, 1895, aged 76, died, Nov 21, 1938, of coronary thrombosis

### "CLINICAL LABORATORIES AND THE AMERICAN CHEMICAL SOCIETY"

*To the Editor*—The editorial "Clinical Laboratories and the American Chemical Society" in *THE JOURNAL* February 4 interests me. I infer that the work of clinical laboratories is "principally a commercial problem ancillary to the practice of medicine."

Undoubtedly this attitude fully explains why the American Hospital Association feels that the services of radiologists, physical therapists, anesthetists, cardiologists, pathologists and clinical pathologists should be included in group hospitalization projects, since, as has been stated in the journals of the hospital associations, these specialists cannot really be considered as practicing medicine, because they "merely carry out the orders of the practitioners of medicine, are subordinates, and assume no responsibility to the patient." Hence the term "ancillary" in the editorial sponsored by the American Medical Association strikes an ominously resonant note.

As a pathologist and clinical pathologist I find expression difficult under the circumstances. Having entered the field of pathology because I sought factual data relative to the mechanisms of disease, I have reaped a harvest of economic headaches which have only recently begun to clear up. Now I learn that I am in a line of work not only commercial but ancillary!

If pathology and clinical pathology do not constitute the practice of medicine—and some doubt seems to exist—then medicine could get along very well if physicians abandoned these specialties. Even now this branch is not overcrowded by those honestly interested in it as a career, and many definite trends are already seriously undermining the morale of those endeavoring to carry it on.

Chemists are capable of directing and developing the procedures of biochemical laboratories, and many of them possess sufficient clinical knowledge to permit certain biologic interpretations, but it seems quite illogical to assume that training in chemistry qualifies a person in hematology, serology, parasitology, clinical microscopy, bacteriology, and the miscellaneous diagnostic procedures of clinical pathology. Furthermore, it would be the height of absurdity for physicians to abandon pathologic anatomy to a chemist or any one without the necessary clinical training.

The situation in Pennsylvania is most interesting, especially when one realizes that Dr. I. D. Metzger has been the ardent exponent of his present point of view consistently for many years and that he has seldom received the support due him from the medical spokesmen of Philadelphia and of the state at large. It certainly behooves the learned profession of medicine to support him now.

The American Board of Pathology is now an accomplished fact and an integral unit of our national medical organization. By this board the specialties of pathologic anatomy and clinical pathology are clearly defined. Much work and a large field in the practice of medicine now belong to the certificated pathologist. There exist no other specialties that are not dependent on him to a very appreciable extent. His field, like that in other specialties, can be closely guarded to prevent exploitation.

Much of the present structure of modern scientific medicine is founded on the work of pathologists and clinical pathologists. We have only recently embarked on the development of our own American culture in these sciences which now analyze the mechanisms of disease. If they are turned over too completely to nonmedical personnel because we are somewhat dubious as to their status in the practice of medicine, such doubt might not long be entertained by the nonmedical group who take them over.

NORMAN W. ELTON, M.D., Buffalo

### SULFANILAMIDE IN THE PREVENTION OF PUERPERAL INFECTION

*To the Editor*—May I call your attention to a probable error in the communication "Sulfanilamide in the Prevention of Puerperal Infection" from your Paris correspondent, *THE JOURNAL*, February 4, page 459.

In an abstract of Dr. Picot's thesis, appearing in the *Presse medicale* (46 1935 [Dec 31] 1938), it is stated unequivocally that the drug used was not sulfanilamide but a derivative, *p*-benzylaminobenzenesulfonamide, commercially known as septazine. The title of this abstract reads: Guy Picot Contribution à l'étude de la prophylaxie de l'infection puerperale. Essai de chimiothérapie préventive (Benzyl-Amino-Benzene Sulfamide) [Travail de la Clinique Tarnier].

JENNIE PINCHACK, New York

Librarian, E. R. Squibb & Sons

### "ORCHITIS AFTER MUMPS"

*To the Editor*—Anent "Orchitis After Mumps" (*THE JOURNAL*, January 14, p. 170), I reported a case (*THE JOURNAL*, Sept. 2, 1916, p. 741) in which I grafted a piece of testicle into remnants of such a lost testicle in the hope of at least restoring a masculine voice to a man who had lost it with his testicles. The effect of the graft restored the voice in a surprising way not by physical presence but because it stimulated remains of the destroyed testicle into nearly normal development. I showed the patient at a meeting of the New York Surgical Society and the case was held to be more important than my case of pregnancy after ovarian grafting, the latter a case in which the tissues of the receptor happened to be taken out of foreign tissue. Later I tried various experiments for instituting tolerance but failed in that quest, I hope some one will do it. In my eighties I am past all useful work with the exception of stories for the boys when they make welcome calls.

ROBERT T. MORRIS, M.D., Stamford, Conn.

### A COMMENT ON BIOLOGICALLY CORRECT TRAFFIC EQUIPMENT

*To the Editor*—A recent interesting note (Fabing, H. D. A Neurologic Note on Traffic Lights. *THE JOURNAL*, Sept. 24, 1938, p. 1166) stressed the need for biologically, physiologically and psychologically sound technique for making our machine age civilization fit the human being who has to use and enjoy it. Quite rightly it was held that traffic is one of the important fields in which such techniques are necessary. This principle can and should be applied to the various problems arising from traffic facilitation and control. It is unfortunate, however, that the article goes on to recommend as biologically sound a type of traffic signal which has been tried out and discarded.

The type of signal recommended was of the clock type in which a hand indicates how much time the red, yellow or green will remain showing. This type of signal and its variations have been discarded for several reasons, one of the chief being one of practical motorist psychology. That is, it has been found that when a motorist is given a warning that a light is about to change he tends either to "beat the light" or to "run through the yellow," depending on whether he is stopped or is moving. This is a psychologic feature to be avoided, since it results in collisions.

Avoidance of the difficulty was provided by the committee of traffic experts who drew up the Manual for Standard Traffic Control Devices (American Association of State Highway Officials and National Conference on Street and Highway Safety, Manual of Uniform Traffic Control Devices, Washington, D. C., 1937). The manual recommends a warning yellow only for the driver who is coming to a halt.

The author contended that the standard three color signal was hard on the nervous system and cited increased heart beat, sweating and other autonomic nervous signs of being under strain. Of course, such nervous tension may occur in varying degrees under various situations. A ball game, the approach of a pretty girl, lack of experience in handling a car and many other factors might produce similar results. Color blindness might make it difficult for a driver to distinguish between the red and the green signal and thus cause extra strain. If so, he would do well to note that the standard code places the red signal always at the top of the three signal lenses and to advocate adoption of the standard in all cities where this has not yet been accomplished.

Certainly this nervous reaction to the standard signal cannot be explained on the basis of Pavlov's "conditioned neurosis" experiments unless some special condition such as color blindness is present. Pavlov's studies were quoted quite correctly as producing "neurotic" behavior on the part of a dog trained to obtain food at one signal and avoid it at another. It should be noted, however, that the dog was first trained to widely different signals and then gradually the two opposite signals were made more and more alike or else the signals were alternated continuously and rapidly so as to be practically simultaneous from the dog's point of view. The "neurosis" occurred when the two signals became very similar, that is, when the animal was unable to distinguish them with any certainty. In other words, the task became too difficult for the animal to perform with his natural ability. This result has been investigated further and confirmed more recently by American investigators (Anderson, O. D., and Liddell, H. S. Observations on Experimental Neurosis in Sheep, *Arch. Neurol. & Psychiat.* 34: 330-354 [Aug.] 1935; Liddell, H. S. The Experimental Neurosis and the Problem of Mental Disorder, *Am. J. Psychiat.* 94: 1035-1043 [March] 1938).

Certainly the average motorist has no difficulty in distinguishing between the red and the green of the standard signal light at an ordinary intersection, nor are they alternated in such a fashion that he is unable to tell what he is being commanded to do. Thus, the comparison of the human response to the red and green signals with the animal's response to signals which were undistinguishable does not hold.

Now let us return to the possibility of color blindness. Color blindness is known to affect but a relatively small percentage of the population, but it is quite possible that the colors used in some of the lenses on the market could be improved for the benefit of the red-green blind person.

Otherwise it seems that the present three color traffic signals as recommended by the Manual of Standard Traffic Control Devices are fairly well suited to the psychologic and physiologic requirements of the ordinary driver.

On the other hand, the contention that traffic facilities and control devices must be psychophysiologically and psychologically fitted to the needs of the driver certainly should apply to all phases of traffic. This means that in the design and installation of such facilities and equipment it is necessary to consider the psychology and physiology of vision, of the ability to read signs, of human inertia, of fatigue, of muscular skill and manipulation, of distraction and attention and of the effect of uncertainty on the driver's reaction time.

For instance directional signs at highway intersections must be of such size, letter design and text organization as to be read by the motorist when he is still a long distance away. He thus will have time to make up his mind as to what he is going to do and be able to do it without sudden turns or stops and their attendant collisions and accidents.

Again, highway lighting should be of such adequacy either from headlights or from overhead lighting that the driver will be able to see and act quickly. It has been shown that any uncertainty of vision whether from lighting or from other factors, reduces the speed of decision and action of the driver.

As another example, a clear view of the road ahead should be provided for a sufficient distance to allow safe passing and stopping at the speeds used on the highway. This means a distance which will allow time for perceiving and judging the speeds of oncoming cars, for passing the car ahead and for safe clearance at the end of the pass. Such passing distance, of course, cannot be provided at all points along the road, and at points where this is impossible the requirement should be for sufficient clear distance to give the driver time enough to execute a safe stop.

Strides toward all these objectives have been and are being made, although there is still much to be desired. I agree with Farning that the goal is highly desirable and efforts should be made to achieve it.

T. W. FORBES, PH. D., New Haven, Conn.  
Bureau for Street Traffic Research

## Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

### POISONING FROM AIRPLANE DOPES

To the Editor—A patient works in an airplane factory where he is exposed to the fumes of airplane dope. Does this dope give rise to any symptoms? If so, what symptoms? The patient gets better slowly after lying off from work. C. W. BURGWIN, M. D. Guy's Mills, Pa.

ANSWER—During the period of the great war and for several years afterward one of the foremost industrial health problems centered about the chemical coating for fabric airplane wings. At that time poisonous materials were utilized. "Dope poisoning," an inelegant and medically undesirable term, was real, frequent and serious.

At the present time larger planes are almost uniformly provided with metal wings and other metal housings. Smaller planes, and particularly model planes and toys, make use of fabric wings and housings, so that "dopes" are still in some use. However, the chemical composition is changed, so that the earlier used toxic substances largely have disappeared. Lacquers are in wide use and these ordinarily contain various acetates, alcohols and toluene. Lacquer vapors are comparatively harmless, although the various acetates are minor respiratory irritants and toluene, if present, may lead to more extensive systemic damage. Toluene is in the series of coal tar hydrocarbons that includes benzene and xylene. Toluene is less dangerous than benzene, since it has a high boiling point and thus evaporates less freely. The action of toluene is somewhat similar to that of benzene and, if it has led to chronic involvement, blood changes may be expected including anemia and leukopenia. This comment refers in general to lacquers such as are used on airplane fabrics, but in the present instance if any other 'dope' than lacquer is utilized a special investigation of the particular product should be instituted.

### MALE HORMONE IN HYPERTENSION

To the Editor—One of my patients asked me about the effect of injections of male sex hormones (testosterone propionate) as a treatment for arterial hypertension. He told me that some of his friends had used this kind of therapy successfully. What is your opinion?

MANFRED LANDSBERG, M. D. Cudahy, Wis.

ANSWER—There are no recent American reports on the administration of testis hormones in hypertensive arterial disease. From Vienna Steinach and his co-workers (Steinach, E., Peczenic, O., and Kun, H. *Wien klin. Wchschr.* Jan. 28, 1937, and Feb. 4, 1937) report reduction of the systolic tension in thirty-one of forty-nine male patients treated with androsterone benzoate. Reductions of the diastolic tensions were negligible. Greene (*Lancet* 2: 79 [July 9] 1938) reports that in twenty-one male patients between the ages of 58 and 77 there was no significant change in the arterial tension after long and liberal

administration of testosterone propionate The 'before and after' variation of the diastolic tensions averaged from 3 to 4 mm Thus the literature appears to deny any useful place to the testis hormone in the management of hypertensive disease This is to be expected, for there has been no evidence indicating that diminution of the testis hormone or hormones has any etiologic significance in hypertensive disease The primary principal of therapy involves the removal or at least the amelioration of etiologic factors These must be searched for they vary in each individual case

#### ERYTHROCYTE SEDIMENTATION IN CORONARY OCCLUSION

To the Editor—In a case of coronary thrombosis sedimentation rates taken during the week persistently show a fall of 2 mm in forty five minutes The patient during this period has been on morphine medication Would drug therapy such as morphine influence the sedimentation rate or is it possible that the rate is not influenced in coronary thrombosis until from seven to ten days after the onset of the occlusion?

LEO KELLER MD New York

ANSWER—While an increased erythrocyte sedimentation rate is a constant finding in coronary occlusion, it is not safe to say that a normal sedimentation rate is an impossibility There are other conditions in which an increased sedimentation rate is almost constantly present (notably active tuberculosis) yet occasionally a normal sedimentation rate will be found A considerable number of proved cases of coronary occlusion have been studied with especial reference to the sedimentation rate Numerous observations were made in each case These studies have shown an increased sedimentation rate in all proved cases of coronary occlusion at some time during the course of the disability In some instances the increased rate first appeared toward the end of the second week There is little likelihood that morphine would affect the sedimentation rate

#### STARCH IN GLUTEN BREAD—MIXTURES OF DIFFERENT TYPES OF INSULIN

To the Editor—What is the amount of starch in ordinary gluten bread as compared with ordinary white bread made of the standard flour? What would be the proportion by weight or by volume of gluten bread as compared to white wheat bread? Is there any objection to mixing various types of insulin for instance as a combination of regular insulin with solution of zinc insulin crystals? I find that I may (not yet proved) get what I wish by a combination of 5 or 8 units of regular insulin with 15 or 18 units of the solution of zinc insulin crystals mentioned I am striving to get a one hypo a day combination I have tried all sorts of ways but seem now to be approaching success This I do by using a single needle which is used to give the small preliminary dose of regular insulin which acts promptly and will be effective until the slower solution of zinc insulin can come into the battle The zinc insulin solution reaches its maximum effect in about eight to nine hours Protamine zinc insulin while theoretically perfect for the one hypo a day does not in my hands give that result The daily dose is administered in the morning around 7 30 Two needles are used The first is left momentarily sticking in the flesh while the second is used only to extract the required dose of zinc type insulin The second needle is then removed the syringe slipped into the first needle still in the flesh and the dose injected slowly We are told not to mix various types of insulin but I can see no adequate logic in that admonition

MD Pennsylvania

ANSWER—The usefulness of gluten breads and other so called diabetic foods is limited as described in the General Decision of the Council on Foods (*THE JOURNAL* Feb 11, 1933 p 411) Gluten breads are not uniform The average of several analyses of wheat gluten bread shows the carbohydrate to be 28.9 per cent or approximately 30 per cent in contrast to the average of analyses of wheat bread which is 52.6 or approximately 53 per cent From this one might conclude that the carbohydrate in gluten bread was about three-fifths that of wheat bread The subject however, is not quite so simple, because the wheat gluten bread averages 25 per cent protein in contrast to the average wheat bread which contains 9.2 per cent protein A diabetic patient may convert 58 per cent of the protein into carbohydrate Consequently out of 100 Gm of gluten bread one would have  $25 \times 58 = 145$  Gm carbohydrate formed in contrast to  $9.2 \times 58 = 533$  Gm of carbohydrate derived from 100 Gm of wheat bread The content of fat in the two kinds is different Wheat gluten averages 3.6 per cent of fat and wheat bread 1.3 per cent However only 10 per cent of carbohydrate would be formed out of fat

In general it is safer to teach patients to use a standard wheat bread and if they do not employ scales they may be able to buy wheat bread which is either sliced or marked for slices so that

each slice contains 30 Gm (1 ounce) and in it would be found from 16 to 18 Gm of carbohydrate according to whether one figures the carbohydrate alone or that derived from carbohydrate, protein and fat The variation in carbohydrate in different makes of gluten breads is considerable

Theoretically there would appear to be no reason why one should not use regular insulin, protamine zinc insulin and a solution of zinc insulin crystals together While various attempts have been made to do this, such as the ingenious one described it has usually not been found practical in the treatment of large groups of cases, because there are so many variables in the chemistry of insulin and the treatment of diabetes

#### HAZARD FROM AMMONIA FUMES IN BEAUTY SHOP

To the Editor—A patient has a cough which for a short time was accompanied by hemoptysis I have made the usual complete studies and am treating her with satisfactory results thus far The diagnosis is fibroid phthisis However there is a question of occupational hazard involved She owns a beauty shop She states that she has been exposing herself to fumes of ammonia for more than ten years in the process of permanent waving She has noticed a tendency to cough whenever she is exposed to these fumes and she states that the other operators also are disturbed by them 1 Could this be an etiologic factor in any form of pulmonary disease? 2 What part might this play as a predisposing or aggravating factor in pulmonary disease? 3 Are there any precautionary measures which can be used to minimize these dangers?

MD West Virginia

ANSWER—1 In some permanent waving work cloth pads wet with aqueous ammonia are wrapped about strands of hair and then enclosed in electrical heating units, which bring about evaporation of the liquid present and lead to artificial waving This process lasts about fifteen minutes and it is the lot of many women to have coughed, sneezed, retched and shed tears as a result of this exposure to ammonia vapors—all in the quest of beauty Naturally beauty shop operators are more extensively exposed because of frequent repetition of the process As little as 400 parts of ammonia vapor per million of air will cause immediate irritation of the throat, and 100 parts per million is the maximum that should be tolerated in prolonged exposure On entering the respiratory tract ammonia immediately reacts with the tissue there present but only superficially Ammonia as such is not absorbed High concentrations of ammonia lead to spasm of the glottis and are thus irrespirable Lower, but still high concentrations may lead to extensive damage along the respiratory tract, chiefly characterized by pulmonary edema Action on the heart and respirations constitutes a reflex from local action along the respiratory tract In connection with severe coughing, bloody mucus may be produced, but the direct causation of an extensive hemoptysis is most improbable

2 It is well known that prolonged coughing aggravates almost any pulmonary disease including tuberculosis Hence it may be believed that long or frequent exposures to comparatively low concentrations of ammonia may aggravate many types of pulmonary disease

3 The prevention of this injury is simple by elimination of this type of permanent waving Other chemicals may be utilized for the same purpose, some at least of which are not injurious

#### ACRODERMATITIS CHRONICA ATROPHICANS

To the Editor—Please tell me the treatment for acrodermatitis chronica atrophicans

MD Ohio

ANSWER—The inquirer undoubtedly has reference to the entity called acrodermatitis chronica atrophicans This is one of the idiopathic atrophies of the skin It is a diffuse process and as its name indicates, favors the extremities, particularly the extensor surfaces

The essential cause of this atrophy is not known Some believe that the atrophy is due to a trophoneurosis Others feel that mechanical chemical or thermal insults acting on a predisposed skin are at fault Infections particularly tuberculosis and syphilis are blamed Lastly, disturbance of the endocrine glands is supposed to underlie acrodermatitis atrophicans

The skin should be protected from injury of exaggerated thermal changes, irritants of various kinds and trauma Foci of infection should be sought and eradicated Tuberculosis and syphilis if present should of course receive appropriate attention The entire nervous system should be examined Administration of thyroid or one of the other glandular substances or products can be considered if examination of the patient warrants it otherwise Local emollient applications can be used such as borated cold cream equal parts of hygroscopic wool fat and petrolatum olive oil, and liquid petrolatum

## INGESTION OF SOAPS

To the Editor—Please discuss for me the possible harmful effects following the ingestion of soap. Please furnish references to the literature.  
M D Texas

ANSWER—Soaps are the salts of fatty acids and bases. The fatty acids of ordinary soaps are oleic, palmitic and stearic. They combine with bases to form soaps soluble or but slightly soluble in aqueous mediums. The soluble soaps are compounds of potassium and sodium, the less soluble are of magnesium and calcium. The harmful effects from the ingestion of solutions of the soluble soaps depend on the concentration, the amount of free alkali and the soap itself. Dilute solutions in small quantities are harmless. The harmful effects of solutions with appreciable amounts of free alkali are due mainly to the corrosive action of the base on the mucous membranes of the digestive system and with aspiration, of the respiratory passages. Hartmann (according to Else Petri, Friedrich Henke and Otto Lubarsch, *Handbuch der speciellen pathologischen Anatomie und Histologie*, Berlin, Julius Springer, 1930, vol 10) concluded from experiments in animals with 0.5 per cent solutions of neutral potassium and sodium soaps that the necrosis and inflammation were due to the soap molecule, not alone to the alkali. The cause of sudden death from the ingestion of soap (Liebtrau *M Klin* 2 1228, 1906) is not clear, especially when the alkali content of the soap is small. Death of these patients has been ascribed to a generalized or blood toxic action, the latter in the sense of a hemolysis. The insoluble soaps in small quantities probably have no deleterious effects. The gastric secretions slowly convert the soap into free base and fatty acids (Hartsuch, P J. The Chemical Reaction Between Oleic Acid and Aqueous Solutions of Magnesium, *Arch Path* 25 17 [Jan] 1938). The effects of fat tissue hydrolysis and soap formation in the body is another problem (Hirsch, E F. Experimental Tissue Lesions with Mixtures of Human Fat, Soaps and Cholesterol, *ibid* p 35).

## FAMILIAL NYSTAGMUS

To the Editor—Recently while examining a group of preschool children I found two little girls of 5 and 6 (sisters) with a horizontal nystagmus. I could not elicit abnormalities of gait or tremors but all deep tendon reflexes were exaggerated. The mother says the children's father, their grandmother on the paternal side, two aunts on the paternal side and two first cousins about the same age have the same type of nystagmus. I have been unable to investigate the history except to ascertain that the father does have a horizontal nystagmus. Could you tell me whether there is a familial central nervous system lesion which could cause this? Are there similar histories on record? I should like to continue my investigation but wish to know whether it would be worth while and also wish I could have some idea as to diagnosis.  
M D Wisconsin

ANSWER—There is a familial central nervous system disease known as spasmus nutans in which nystagmus occurs in children especially when the head is fixed. There may be a nodding movement of the head in association with the nystagmus as well as strabismus and blepharospasm. The condition was first described by Barton, Bennet and Newnham. All these increased movements may occur in children who come from a family with a history of neuropathic traits or diathesis. It would be well worth while to study the two cases as well as the family and report in detail. The condition is due, no doubt, to an inherited or a congenital instability of the nerve centers supplying these structures.

## CUPREX FOR PEDICULOSIS

To the Editor—What is your opinion on a preparation for exterminating lice and nits called Cuprex put out by Merck & Company? Is there any advantage in using this over the older remedies? Are there any dangers attended by its use?  
M D New York

ANSWER—Apparently the composition of Cuprex has not always been described in the same manner. It is described in Merck's Index (1930) as 'a solution of a copper compound in organic solvents—clear, pale green, inflammable liquid.' According to Bresslau (*Ber Ges Physiol exper Pharmacol* 32 912, *Chemical Abstracts*, 1926, p 2223) Cuprex is a solution of copper salts of fatty acids. Schnellbach (*Schweiz Apoth Ztg* 64 91, *Chemical Abstracts*, 1926, p 2391) states that Cuprex is a solution of copper abietate in a mixture of benzene and paraffin oil. The most recent statement of the composition of Cuprex is the following, received from the manufacturer in November 1937: "liquid petrolatum 20 parts, tetralin (tetrahydronaphthalene) 12 parts, acetone 6 parts, and copper oleate 'fraction of a per cent'."

Merck & Co call attention to the inflammability of Cuprex and to the general irritant properties of all pediculicides which render their use for more than one or two applications inadvisable.

Although Cuprex has been marketed in this country for more than ten years, the files of the Council on Pharmacy and Chemistry, as well as the files of other available sources, reveal no published papers dealing with the comparative value of this preparation and other commonly used pediculicides.

Much information concerning various methods employed in the eradication of dermal parasites may be found in the special articles published in *THE JOURNAL* Oct 3, 1936, page 1126, and Feb 13, 1937, page 553. An interesting chapter on the treatment of pediculosis may also be found in the *Handbook of Therapy*.

## HEAD SHAVING AND HAIR GROWTH

To the Editor—Have you any information regarding whether or not by keeping the hair shaved from a baby's head for a period of twelve months or more the hair finally allowed to grow will be heavier in texture?

ARTHUR L. RICHARDSON, M.D., Pasadena, Calif.

ANSWER—There is no evidence that shaving causes hair to grow more thickly or changes in any way the texture of the hair. The only effect is that of moderate stimulation of the scalp, which benefits hair growth.

## BENZIDINE TEST FOR BLOOD

To the Editor—What reaction takes place and what is the name of the blue product formed when benzidine and barium peroxide in diacetic acid (50 per cent) give a positive test for occult blood in the stool?

RAYMOND H. GOODALE, M.D., Worcester, Mass.

ANSWER—The benzidine test for blood involves the oxidation of benzidine to a colored compound or mixture of compounds of unknown structure as the result of the combined action of peroxide and the iron in the hemoglobin. To eliminate the error from a positive test by other iron compounds, it is best to make the following modification: Add 2 cc. of glacial acetic acid to 5 cc. of the feces suspension and allow the mixture to digest at room temperature for from fifteen to thirty minutes, strain or filter and shake the filtrate with 5 cc. of ether. Separate the ether layer and apply the benzidine test, preferably by adding 2 cc. of a freshly prepared saturated solution of benzidine in glacial acetic acid to the ether solution plus 0.5 cc. of solution of hydrogen peroxide U.S.P. Mix well. Development of a blue appearance in from two to three minutes is a positive test for blood due to the hematin extracted by the ether.

## CARBON TETRACHLORIDE

To the Editor—I should like to ask you to publish a correction to a statement made in your July 30, 1938 issue. The first query on page 469 of your answer has just been brought to my attention. In speaking of the use of carbon tetrachloride extinguishers you state in the third paragraph of your answer that its vapors in concentrations above 100 parts per million of air may produce damage. When the concentration reaches 1,000 parts per million immediate injury is in prospect for persons who may breathe this vapor even for a few breaths. If you will refer to my article in *THE JOURNAL* for Nov. 21, 1936 under 'Comments and Conclusions' page 1686 you will see that 'it is concluded that 100 parts per million of carbon tetrachloride is a safe working concentration for continuous exposure of workmen during the working day (eight hours a day, five days a week). Concentrations considerably higher than 100 parts per million are safe for short periods. It is believed that 1,000 parts per million is a safe peak concentration for half an hour a day (probably much longer than the user of a fire extinguisher would be exposed), with an average of 100 parts per million during the rest of the day. I agree with your last paragraph, in which you state that although these extinguishers may be theoretically dangerous they rarely lead to an accident. Your advice to use the extinguisher as quickly as possible and then to leave the area is a good one but not because of the danger of phosgene alone. Under the conditions in which phosgene would be formed (great heat, metal surface closed space) there is likely to be at least as great a hazard from carbon monoxide poisoning which would be present regardless of the method used to combat the fire.'

HENRY FIELD SMITH, M.D., DR. P.H., Philadelphia

## VAGINAL ABSORPTION

To the Editor—In the January 14 issue of *THE JOURNAL* on page 173 under Queries and Minor Notes under the heading 'Absorption from Vaginal Mucosa and Uterus' the answer states that there is no absorption from the intact vaginal mucosa. This statement is not quite correct since it is known that the intact vaginal mucosa absorbs many substances. For example, vaginal suppositories containing estrogenic substances are constantly used and many other substances are known to be easily absorbed through the vagina. It is quite possible that toxins from bacteria are absorbed through the same route just as they are from other mucous membranes.

WILLIAM WOLF, M.D., New York.

## NATIONAL BOARD OF MEDICAL EXAMINERS SPECIAL BOARDS

Examinations of the National Board of Medical Examiners and Special Boards were published in THE JOURNAL February 25 page 767

## Montana October Report

Dr S A Cooney, secretary, Montana State Board of Medical Examiners, reports the written examination held at Helena, Oct 4-5, 1938. The examination covered ten subjects. An average of 75 per cent was required to pass. Six candidates were examined, all of whom passed. Eighteen physicians were licensed by reciprocity and five physicians were licensed by endorsement. The following schools were represented:

School	PASSED	Year Grad	Per Cent
College of Medical Evangelists	(1938)	88 1	
Loyola University School of Medicine	(1929)	82 9

## Book Notices

**Research in Mental Hospitals A Survey and Tentative Appraisal of Research Activities Facilities and Possibilities in State Hospitals and Other Tax Supported Institutions for the Mentally Ill and Defective in the United States** Conducted by the National Committee for Mental Hygiene 1936 1937 Paper Pp 1+1 New York City 1938

By information collected through questionnaires, personal interviews and visits, a survey was made of existing facilities for research in mental problems in private hospitals and public institutions. This book constitutes an appraisal of that review. It was found that twenty of the 273 public institutions could be designated as research centers because of the character and quality of their investigatory work the caliber of their personnel and the resources at their disposal for scientific study. In addition there are thirty-two public-supported hospitals that offer distinct possibilities for research work. Furthermore the report estimates that there are 150 of the 1700 staff physicians in the public mental institutions of the country who show a definite interest in and ability for investigative work. The survey furnishes tangible evidence that a creditable beginning has been made in the development of research in public institutions and that further desirable expansion might be fostered with moderate encouragement and financial support. The extension of research, the report concludes, will be dependent in large measure on the availability of men with eager and inquiring minds who possess the qualifications for exploratory endeavor. In other words, many institutions can be encouraged to devote further efforts to psychiatric research, but the most important method of extending desirable investigative studies appears to be by encouraging recent graduates in medicine whose records would indicate promising careers in psychiatric research to enter this field.

**Cranio Cerebral Injuries Their Diagnosis and Treatment** By Donald Munro A.B. M.D. F.A.C.S. Surgeon in Chief for Neurological Surgery at the Boston City Hospital Boston Cloth Price \$4 Pp 412 with 62 Illustrations New York Toronto & London Oxford University Press 1935

The increasing number of head injuries resulting from automobile accidents in all sections of the country has forced on almost every practitioner of medicine the necessity of treating them. The treatment of craniocerebral injuries has passed through several stages of development and as a result many conflicting hypotheses based on erroneous observation have been advanced. For that reason Munro's book fills a much needed place in a medical library a book to which the physician can refer for specific information concerning the most efficient methods of dealing with craniocerebral injuries. In the introduction Munro calls attention to the fact that the approximate number of fractured skulls in 1932 was 112,000. Unquestionably this number must be increasing and therefore the impracticability of expecting the few neurosurgical clinics of this country to care adequately for so many seriously injured patients is apparent. Munro is of the opinion that the problem of craniocerebral injury belongs to the general surgeon and that the neurologist and neurosurgeon should be consulted in the more complicated cases. This, of course, places a great responsibility on the general surgeon and makes it imperative that he acquaint himself with the most effective methods of treatment and provide himself with the necessary hospital and staff equipment. In this book an endeavor is made to present the information necessary for the general surgeon who either elects or is forced to treat craniocerebral injuries. It implies neither specialized knowledge nor technical skill. It has proved its worth in practice over a number of years and in a large active traumatic clinic. The book is based on experiences accumulated by all members of the staff, from house officers and residents to the chief of the service, and the methods that it describes have been equally effective in the treatment of patients suffering from craniocerebral injuries whether used by the most recent newcomer to the hospital or by any of his seniors. As a background for his discussion of the problem the author first elaborates on the

fundamental cerebral physiopathology and then proceeds to the importance of history and examination of the patient. A chapter on roentgenology precedes the chapters on general principles of treatment, which are followed by chapters on special nonoperative and operative methods of treatment. Chapters on the nonoperable and operable groups of craniocerebral injuries are followed by a discussion of the complications due to necessary treatment and a most important chapter on convalescent care. A chapter on craniocerebral injuries of the newborn is a valuable addition to the general discussion. The final chapters, on first aid in craniocerebral injuries and the mortality and morbidity statistics with illustrative cases, complete this most interesting and valuable book. The volume should be in the library of every physician who attempts either by choice or by necessity to treat injuries of the head, for it makes a working knowledge of this subject available in a simple and comprehensive form.

**The Medical Applications of the Short Wave Current** By William Bierman M.D. Attending Physical Therapist Mount Sinai Hospital New York City Including a Discussion of Its Physical and Technical Aspects By Myron M. Schwarzschild M.A. Physicist Beth Israel Hospital New York City Cloth Price \$5 Pp 379 with 55 Illustrations including 9 plates Baltimore William Wood & Company 1938

There has been much unjustified and largely commercially inspired enthusiasm about the alleged specific therapeutic value of short wave diathermy. This volume is the well directed result of the combined efforts of a competent physical therapist and a physicist with special interest in medical electricity for a critical and broad portrayal of the present status of this new physical therapeutic agent. A short introductory chapter on the history of high frequency therapy is followed by 102 pages of scholarly and exhaustive discussion by Schwarzschild of its physical and technical aspects. In the chapter on physiologic responses Bierman takes the same stand as other conservative observers that the primary action of the current is essentially due to the heat developed and that so called nonthermal or specific effects are still to be proved. There is a large and fairly well illustrated chapter on technique. The final and largest chapter deals with clinical application, giving a comprehensive summary of the uses of short wave diathermy along the entire realm of pathology based on the author's own experience as well as on reports in the international literature. Bierman's special field of research, fever therapy by means of short waves, receives exhaustive attention in this and in the preceding chapters. Students of physical therapy and interested clinicians will find an unbiased and large store of information in this excellent volume.

**New Jersey Formulary (N J F)** Compiled and Published by the Joint Committee on Professional Relations Consisting of the Committee on Pharmaceutical Problems of the Medical Society of New Jersey and the Committee on Professional Relations of the New Jersey Pharmaceutical Association Chester I. Ulmer M.D. Chairman Robert P. Fischell Pharm.D. Editor Third edition Paper Pp 64 Trenton New Jersey 1939

This booklet opens with suggestions to physicians which include a plea for prescription writing in place of the prescribing of controlled name products. This section includes the statement that "to combat commercial domination of therapeutics the Council on Pharmacy and Chemistry of the American Medical Association was formed. Physicians should avail themselves of the help which their own Council can give them." The booklet contains the usual tables of weights, measures and equivalents and then suggests various preparations which are designated "N J F" (New Jersey Formulary). These are essentially modifications of the National Formulary preparations included in the book. Typical prescriptions are given for sedatives, elixirs, analgesic capsules, tonics and carminatives. The general purpose of this book is excellent. The advisability of suggesting prescriptions to physicians has certain advantages and also certain disadvantages. One item which is obviously designed to supplant expensive proprietary preparations of this type is a baby oil, "Olei Infantilis, N J F," which contains 12.5 per cent of olive oil in light liquid petrolatum, with 1 part in 500 of the antiseptic chlorothymol and oil of rose to perfume. On the whole, this booklet appears to be as useful as similar formularies which are on the market. It is especially designed

however, for use in New Jersey, since it contains the "N J F" preparations which those in other states would not be familiar with. The idea of pharmacists and physicians cooperating in the preparation of such a book is preferable to the plan used in one other state of issuing such information from a joint committee of the Pharmaceutical Association and the Retail Druggists Association.

**Diseases of the Ear, Nose and Throat.** By Francis L. Lederer, B.Sc., M.D., F.A.C.S., Professor and Head of the Department of Laryngology, Rhinology and Otolaryngology, University of Illinois College of Medicine, Chicago. Fabrikoid. Price \$10. Pp. 885 with 457 illustrations including 16 color plates. Philadelphia: F. A. Davis Company, 1938.

To the available American textbooks in the field of otolaryngology may now be added a fine contribution by Dr. Francis L. Lederer of the University of Illinois College of Medicine. The textbook mechanically presents several features not available in other works, including excellent illustrations and innumerable black and white pictures, arrangement in two columns for easy reading, presentation in simple outline form which is a great aid to the medical student, and the collaboration of specialists in many of the chapters, which provides exceptional authenticity. Each of the sections is prefaced by a compact consideration of the special anatomy concerned. The diseases are considered in the classic oslerian form of definition, etiology, bacteriology, transmission, epidemiology, symptoms, prophylaxis and treatment. There are no references to bibliography or to individual authorities, the author taking full responsibility throughout for the statements that are made except for the recognition given in the preface. Perhaps for the medical student this is an ideal form. The index is detailed and exceedingly useful. The methods of treatment follow those generally accepted as established. Special recognition should be given to the pupils of Mr. Tom Jones, whose contributions to the illustrations are unique.

**Dr. Ida, India: The Life Story of Ida S. Scudder, M.D., B.Sc., F.A.C.S., K.I.H., President, Medical College for Women, Vellore, India.** By Mary Pauline Jeffery, M.D. Cloth. Price \$2. Pp. 212 with 19 illustrations. New York, London & Edinburgh: Fleming H. Revell Company, 1938.

American physicians who are inclined to feel pessimistic should read this story of their valiant colleague in Vellore, India. Dr. Ida Scudder, daughter and granddaughter of medical missionaries, decided there had been enough Scudders on the mission field and she was going to remain in America after her schooling was finished. Even when her mother became ill and she had to return to India to assist her father in the mission in remote Tindavanam, she went as a short-term missionary. It was while there that she experienced the heart-breaking experience which changed the course of her life. Three times in one night she heard Indian men refuse her father's services for their child wives in desperate labor, and the next morning she watched the funerals of the three girls as they passed the Scudder home. It was after a day of "much thought and prayer" that she made her decision to study medicine that she might help Indian women. Years later, Jan. 1, 1900, she landed again in India, bringing with her \$10,000 for the building of a hospital for women. While that first hospital was being built, Dr. Ida found her hands full, fighting the black death, then cholera and leprosy, and other afflictions of the Orient. Through the years that have followed, disease has been only one of her enemies. She has had to battle the shocking worship of the goddess Kali, the ignorance of charm doctors and the traditional system of medicine known as Ayurvedic, child marriage with its accompaniment of immature motherhood, and the caste system with its scorn of 45,000,000 Untouchables. Through her influence sanatoriums for the tuberculous have been established, a school for nurses started, dispensaries opened, hospitals built, and at last the Women's Medical College in Vellore. A children's home has been cared for by Dr. Ida herself with two of her colleagues. From a lovely, mischievous girl, Dr. Ida Scudder has developed into a poised and understanding woman, quite unspoiled by the praise and admiration accorded her by men and women from all parts of the globe. A tireless woman, always alert to help Indian women to help themselves. The book is interestingly written, not without humor. It should be worth reading from either the medical or the missionary point of view.

## Bureau of Legal Medicine and Legislation

### MEDICOLEGAL ABSTRACTS

**Issuance of Fictitious Diplomas and Licenses to Practice Medicine and Chiropractic as Scheme to Defraud.**—The appellants were convicted under an indictment charging the use of the mails for the purpose of executing a scheme to defraud and appealed to the United States circuit court of appeals, eighth circuit.

In addition to the appellants, five other persons were named defendants in the indictment, but the record does not show what disposition was made of the charges against these other defendants. The indictment alleged in substance that the defendants named therein obtained, prepared and issued to numerous persons fraudulent and fictitious medical and chiropractic diplomas and certificates and fictitious licenses to practice medicine and chiropractic.

The evidence showed that appellant Alexander was secretary of the Eclectic Medical University at Kansas City, Mo., from 1910 to 1915. That school went out of existence in 1916 and was succeeded by the Kansas City College of Medicine and Surgery. The latter college went out of existence in 1926 and was in turn succeeded by the American Medical University. Alexander was custodian of and had in his possession the records of these institutions. Numerous fictitious medical diplomas introduced in evidence came from these schools and were issued by Alexander. The diplomas dating back many years, were issued after the schools had gone out of existence to applicants who never attended the schools. One of the defendants, Laws, was secretary of the Eclectic State Medical Board of Arkansas from 1924 to 1933. He issued many fictitious licenses to practice medicine in that state to applicants most of whom did not pass any examination. Another defendant, Myrtle E. Long, was secretary of the Iowa State Board of Chiropractic Examiners from 1924 to 1934 and, at the request of appellant George M. Lindsay, she issued a fictitious chiropractic license to appellant George M. Lindsay Jr. for the sum of \$250.

Through appellant George M. Lindsay, appellant Debeh secured a fictitious high school diploma, a fictitious medical diploma from the American Medical University, a fictitious certificate of the Arkansas Eclectic Medical Society, and a fictitious medical license from the Eclectic State Medical Board of Arkansas, all for the sum of \$2,500. Large sums of money were paid in most instances for the spurious diplomas, certificates and licenses. Holders of some of the false diplomas and licenses testified that after receiving them they practiced medicine or chiropractic in various states. Debeh practiced in Arkansas, Pennsylvania, Ohio and West Virginia.

The appellants contended that the evidence did not justify their conviction. But, said the court, there was substantial proof of every element of the crime such as to warrant the jury in finding the appellants guilty. Appellants Date R. Alexander, George M. Lindsay and George M. Lindsay Jr. the court said, were the originators of the fraud. The scheme had for its direct object the defrauding of the public. The issuers of the fraudulent instruments acted through and in conjunction with the practitioners to represent to the public that the latter were duly qualified and legally authorized to practice. The interest of the originators of the scheme did not end when they delivered the diplomas and licenses. This is evidenced by the fact that when their false licensees got into trouble with the authorities they tried to aid and assist them to carry on the deception and gave advice in connection with their attempt to continue practice in certain states.

The evidence showed that Debeh knew nothing about the scheme in its inception. He was one of the persons to whom the bogus documents were issued and not one of the persons who issued them. He however knowingly participated in the scheme as evidenced by a signed statement given to a post office inspector in 1935. He declared that in February, 1933 he

had purchased from Lindsay a high school diploma, medical school diploma, certificate of internship and a license to practice medicine in Arkansas for the sum of \$2,500. He then went to Little Rock, Ark., and opened an office. Thus, the court said, the evidence clearly supported a finding that during 1933 and 1934 Debeh was working with the other appellants in furtherance of the scheme alleged in the indictment. The fact that he came in long after the plan had had its beginnings or that he did not take part in carrying out each phase of it did not absolve him of complicity.

After reviewing the record at length, the circuit court of appeals could find no error in it. The judgments of conviction were affirmed—*Alexander v United States*, 95 F (2d) 873.

**Malpractice Amputation of Forearm Attributed to Negligent Treatment of Cut on Finger**—The plaintiff sued the defendant, a physician, for malpractice, alleging that by reason of the defendant's negligent treatment of a finger injury the amputation of his forearm became necessary. The trial court gave judgment for the defendant and the plaintiff appealed to the Supreme Court of Michigan.

The plaintiff cut the little finger and palm of his left hand with a meat saw. About two and one-half hours later he consulted the defendant, who washed the cut with Dakin's solution (dilute solution of sodium hypochlorite) and applied a disinfectant powder. Two stitches were taken in the cut and the wound was bandaged. The defendant testified that he placed a pad underneath the hand and then wound 3 or 4 feet of gauze around it to form what he called a figure-of-eight bandage. He testified that the bandage extended to the wrist and bound all four fingers of the hand together, leaving only the thumb free. The plaintiff and two other witnesses, on the other hand, testified that only the wounded finger had been bandaged and that it was not supported by the other fingers. The plaintiff claimed that he was given no advice as to the care of the hand but was merely told to return for further treatment, which he did. The defendant admitted that he did not tell the plaintiff that the hand should be kept quiet and should not be used. The plaintiff was able to, and did, use the injured hand in driving his car and attending to the work around his farm.

The plaintiff visited the defendant's office several times during the two weeks immediately following the accident. When the wound failed to show signs of healing, the defendant advised the plaintiff to bathe the hand in hot water every two hours, but the plaintiff testified that he did this only several times a day. The hand steadily grew worse, and the defendant claimed that on several occasions he told the plaintiff that there was some infection in the wound and that he should go to a hospital but that the plaintiff stated he could not afford to do so. The plaintiff and his wife testified that at no time did the defendant tell the plaintiff to go to a hospital but that he went of his own accord after the defendant had admitted that the hand might be infected. At the hospital a surgeon first removed two joints of the little finger and thereafter, when the hand and arm became steadily worse, the forearm was amputated.

On appeal, the plaintiff's main claim of error was that the verdict was contrary to the weight of the evidence. Four physicians testified that the treatment given the plaintiff was proper and in accordance with the established practice in the community and like communities. One physician testified to the contrary, and another did not entirely exculpate the defendant from blame. There was evidence that one physician who testified in the plaintiff's favor was related to one of his attorneys. All the physicians agreed that proper treatment required immobilization of the plaintiff's hand and two testified that the failure of the defendant to advise the plaintiff to keep his hand quiet and not use it for work was improper practice. However, the court said, there was testimony to the effect that the defendant might properly have assumed that the bandage which he claimed he applied and the pain which would accompany movement would be sufficient to immobilize the hand without specific advice to the patient. The verdict, in the opinion of the court, was not against the great weight of the testimony.

The judgment for the defendant physician was therefore affirmed—*Moon v Quick (Mich)*, 279 N W 909.

### CENTRAL SOCIETY FOR CLINICAL RESEARCH

Eleventh Annual Meeting Held in Chicago Nov 4 and 5 1933

The President, DR WILLIAM H BUNN, Youngstown, Ohio,  
in the Chair

#### Trichinosis in the Chicago Area

MARION HOOD, PH.D., and S W OLSEN, B.A., Chicago  
Numerous publications indicate that the incidence of trichinosis in the United States is approximately 14 per cent. As no report had been made from the Chicago area a series of 478 cases were studied. The material was obtained from unselected autopsies performed at several Chicago hospitals. Portions of the diaphragm were digested in artificial gastric juice and sedimented. This material was then examined. When approximately 100 Gm of tissue was used, 16 per cent of the specimens were found infected with *Trichina*. The results of this work are in accord with those of surveys from other localities. They show that trichinosis is an important problem in the Chicago area.

#### An Acoustic Study of Stethoscope Behavior

DRS FRANKLIN D JOHNSTON and EDWARD M KLINE, Ann Arbor, Mich. A cadaver with a telephone receiver placed inside the heart was used as an acoustic model to obtain quantitative data regarding the sound transmitting properties of different stethoscopes. The necessary apparatus was arranged so that when the end pieces of different units were placed at the same point on the intact wall of the chest the response over a wide range of frequency was easily obtained. Tests of different end pieces and tubings indicated that 1. The shallow chamber bell is superior to other bells especially for high pitched sounds. 2. A soft rubber nipple placed over the end of a bell improves its performance. 3. The diaphragm on a Bowles unit acts to filter out sounds of low frequency.

but it must be stiff to be efficient in this respect 4 The large Bowles units without the diaphragm are good receptors for sounds of all frequencies and they are further improved when a rubber sheath is placed over the aperture 5 Although changes in the length, the diameter of the hole and the nature of the rubber in different tubes cause some alterations in the response of a given end piece due to phenomena of absorption and resonance, these differences are relatively small

#### DISCUSSION

DR. M. A. BLANKENHORN, Cincinnati I should like to ask the authors if they can explain why the performance is better with a rubber-covered stethoscope bell and if they have studied or plan to study another important function of stethoscopes besides the transmission of sounds, namely that of excluding other sounds and noises which are so easily excluded from the laboratory but are never excluded from the places where one works I should like to ask also if they have studied or plan to study the effects of varying pressure of the bell against the wall of the chest These are all important variables in the hands of the clinician, they are not so important in the laboratory

DR. FRANKLIN D. JOHNSTON, Ann Arbor, Mich When the physician obtains information by the use of the stethoscope a twofold process is involved First, the stethoscope brings sound energy to the ears and he hears certain things Second, by experience and training these sounds are separated and interpreted so that rational conclusions are possible This last process is not measurable, but it is of tremendous importance Nevertheless, an objective study of the behavior of the stethoscope is valuable so that the beginner, particularly, will not be unnecessarily handicapped by the use of an inferior instrument In answer to Dr. Blankenhorn's question about how the rubber nipple placed over a bell improves its performance, I really do not know At first we thought the improvement noted with the nipple was due to a more perfect air-tight seal between the bell and the wall of the chest but this is not the case When the nipple is used the effective area of contact with the wall of the chest is slightly increased, and this may be a factor We did no work relating to extraneous sounds, although at many times during the course of the work vibrations coming through the air and especially through the building proved troublesome I think the only way that extraneous sounds can be dealt with by the physician is through the ability gained, by experience, in disregarding them The tissues of the cadaver were harder than those in the usual living chest, so that increasing the pressure of the shallow chamber units was not likely to obliterate the terminal air space, as may occur with an inexperienced student of auscultation This is an important cause for error and should be pointed out to the beginning student We have no data relating to this matter

#### Neosynephrin in Spinal Anesthesia

DRS. ROBBIE BRUNNER and GEZA DE TAKATS, Chicago The hypotension produced by spinal anesthesia was successfully controlled by the intramuscular injection of neosynephrin hydrochloride in 163 cases For control, 100 cases were selected in which ephedrine sulfate was used for the same purpose Aside from the stabilizing effect of neosynephrin on blood pressure, the tachycardia and restlessness produced by ephedrine were absent, on the contrary, bradycardia was produced by neosynephrin, the mechanism of which is analyzed The drug used with certain precautions and controlled dosage removes one of the great objections to spinal anesthesia, namely the severe fall in blood pressure during and shortly after operation

#### DISCUSSION

DR. K. K. CHEN, Indianapolis There is no question that neosynephrin can be used for the control of the fall in blood pressure in spinal anesthesia When one talks about the ephedrine group, one should think also of the action on the central nervous system Formerly physicians emphasized the effect only on the blood pressure, but now it is evident that the action of this group on the central nervous system must be taken into consideration Freedom from nervous symptoms

is an advantage of neosynephrin over ephedrine However, certain points should be raised and kept in mind First, there is the question of toxicity In our laboratory we found that when intravenously injected in mice neosynephrin is 135 times as toxic as ephedrine The authors use a 10 per cent solution, 0.5 cc would be 50 mg and 1 cc would be 100 mg In other words, they are employing a dose equivalent to that of ephedrine for spinal anesthesia Second the action of neosynephrin is brief, while ephedrine has a much more prolonged effect Before the use of ephedrine, epinephrine and later tyramine were tried for the maintenance of blood pressure I should classify neosynephrin as similar to tyramine The tachycardia under ephedrine depends on the state of the vagus nerve If atropine is injected first, tachycardia follows the use of ephedrine On the other hand, if no atropine is administered, either animals or men usually respond by a slowing of the pulse rate I am certainly much interested in the uniform occurrence of tachycardia with ephedrine therapy

DR. GEZA DE TAKATS, Chicago With the use of this drug we have a safeguard against a fall of blood pressure This has given us a certain degree of confidence, as we have not seen a single instance of lack of response The blood pressure does not always rise, but at least there is no fall We give a small dose at the induction of spinal anesthesia and usually ask the anesthetist to inject the second dose of neosynephrin at the time we note the fall The question of bradycardia was of some interest to us, because most of the patients were elderly and some of them had bradycardia before the operation Clinically we have not observed any untoward symptoms In one case a shifting pacemaker developed When this was observed it was readily abolished with atropine As regards Dr. Chen's question, I should say that the average duration of the pressor effect of neosynephrin is about thirty minutes As far as ephedrine is concerned, most of the patients with spinal anesthesia had either no atropine or only  $\frac{1}{160}$  grain (0.4 mg) subcutaneously We have not noticed any toxic effect with neosynephrin From 0.5 to 1 cc of a 1 per cent solution is used We have used ephedrine for many years with spinal anesthesia Our only objection to the drug is that in a certain group of patients ephedrine produces restlessness, so that it may be necessary to put them to sleep for no other reason

#### Pathogenesis of Hemorrhage in Artificially Induced Fever

DRS. SLOAN J. WILSON and CHARLES A. DOAN, Columbus, Ohio Petechial hemorrhages have been one of the most constant pathologic observations reported following artificially induced fever Necropsy on experimental animals and human subjects following lethal fever has revealed extensive hemorrhages and hepatic damage The mechanism has been attributed to anoxia In the present survey the influence of fever on the circulating blood platelets, prothrombin and fibrinogen have been studied in experimental animals and in the human subject as possibly important additional contributing factors Total platelet counts, qualitative and quantitative studies of megakaryocytes in serial sternal marrow punctures, quantitative determinations of prothrombin and fibrinogen and histologic studies of the liver have been made The hemorrhagic diathesis has been found to be directly proportional to the degree of damage occurring in one or both of these essential factors in the coagulation mechanism

#### DISCUSSION

DR. HOWARD L. ALT, Chicago At present I have under my care a girl aged 7 years who has had artificial fever induced nine times since December 1937 for the treatment of bronchial asthma The last treatment was given three weeks ago Ten days ago she began to have ecchymoses, and at the present time she has all the signs of thrombopenic purpura The platelet count is 20,000 per cubic millimeter In view of the report of Drs. Wilson and Doan it seems possible that there is a relation between the artificially induced fever and the purpura in this case

DR. LEE FOSHAY, Cincinnati Artificial fever therapy has been used and is being recommended for the treatment of

acute and chronic brucellosis. In this infection the brunt of damage to tissue is often borne by the liver, as evidenced by bilirubinemia, urobilinuria, increased prothrombin time, imperfect retractability of blood clots, subserous hemorrhages, occasionally large retroserosal extravasations of blood and often an enlarged and tender liver. I do not wish to be understood as advising against fever therapy in this disease, but I suggest that the facts presented by Wilson and Doan warrant extremely careful selection and preparation of patients with brucellosis before fever therapy is attempted.

DR E P K FENGER, Rochester, Minn. I wonder whether studies have been made of giving oxygen with fever therapy. There is known to be a consumption of about seven degrees of oxygen with fever. If studies were made with a view of giving oxygen with fever therapy it might head off these deleterious effects.

DR SLOAN J WILSON, Columbus, Ohio. Oxygen has been given intranasally during fever therapy to prevent anoxia. Hartman prevented a decrease of oxygen in the venous and arterial blood of experimental animals by the intranasal administration of oxygen. He was the first to suggest that oxygen be given to patients during fever therapy. He also stated that the efficacy of the barbiturates is decreased when oxygen is given.

#### Production of Hepatic Disease by Dietary Deficiency and Its Effect on the Anti-Pernicius Anemia Principle

DR FRANK H BETHELL, Ann Arbor, Mich. Extensive lipoidosis of the liver was produced in pregnant and in non-pregnant rats by diets possessing the relatively low protein contents of 8 per cent and 3 per cent respectively. Associated with hepatic damage there were macrocytic anemia and a megaloblastic reaction of the bone marrow. These changes could not be prevented by oral or parenteral administration of liver extract or by a high intake of yeast. Extracts made from the livers of experimental animals were administered parenterally to five patients with pernicious anemia in relapse. By means of the double reticulocyte response, normal rat liver extract being used as a control, a deficiency of the anti-pernicius anemia principle was demonstrated in the livers of rats made anemic by protein deficient diets.

#### DISCUSSION

DR C J WATSON, Minneapolis. Was the reticulocyte count spontaneously elevated in rat anemia while the hemoglobin and the red blood cell level were falling?

DR O O MEYER, Madison, Wis. I should like to ask whether the livers of the rats on deficient diets were larger than normal, and whether the speaker thought the deficiency in diet was responsible. Also was the extract made from a certain number of grams of liver or was it made by comparing rat for rat? It is possible that the difference in results may be due merely to the factor of dilution.

DR FRANK H BETHELL, Ann Arbor, Mich. In answer to Dr Watson's question, the reticulocyte counts of the rats with macrocytic anemia were elevated. In the rat the number of the reticulocytes fluctuates widely and is increased in almost every form of anemia. With regard to Dr Meyer's question, the livers of the anemic rats were slightly enlarged in proportion to the size of the rats. The doses of extracts were based on the grams of liver from which they were derived not on the weights of the individual rats. The latter method would not be suitable because of the general undernutrition of rats on low protein diets. The weight of the liver of rats on low protein diets was slightly less than that of animals on high protein diets owing in part, at least to the lower specific gravity of fat.

#### Monocytic Leukemia of the Schilling and the Naegeli Type

DRS CHARLES H WATKINS and BYRON E HALL, Rochester, Minn. Two types of monocytic leukemia are now generally recognized—the so called Naegeli type, which many authorities regard as a variant of myelogenous leukemia with a predomi-

nance of monocytes, and the Schilling type, which presumably is a variant form of leukemic reticulo-endotheliosis in which the monocytes are derived directly from reticular cells. In the past ten years we have observed twenty cases of the Naegeli type and four cases of the Schilling type. These two groups of cases are compared with respect to the clinical manifestations (age, sex, presenting symptoms, duration of illness and response to x-ray or radium therapy when either was given) as well as with regard to the hematologic and histologic pictures.

#### DISCUSSION

DR RAPHAEL ISAACS, Ann Arbor, Mich. In myelogenous leukemia immature monocytes may be pushed out of the bone marrow (Naegeli type of "monocytic leukemia") and in monocytic leukemia immature polymorphonuclear cell stages may be forced into the peripheral circulation (Schilling type of monocytic leukemia). Three clinical features help to distinguish monocytic leukemia from the myelogenous type. In the first the liver and spleen are enlarged to about the same linear measurement, whereas in the second the spleen eventually becomes disproportionately elongated. Oral lesions (ulcerative) are more frequent in true monocytic leukemia than in the myelogenous type. True monocytic leukemia responds poorly to roentgen therapy but does respond to arsenical medication. Our present view is that "myelogenous" leukemia which responds to arsenic is in reality monocytic. It is easy to tell the monoblast from the myeloblast or lymphoblast, as the true monoblast is the only one in which granules (red staining) appear in the cytoplasm.

DR BYRON E HALL, Rochester, Minn. There are many different views concerning the origin and developmental potencies of the mononuclear elements in the blood and blood forming organs. This is particularly true of the monocyte. However, we feel that the separation of monocytic leukemia into two groups is justified not only on the basis of the difference in the blood picture and the type of stem cell from which the monocyte is derived but because of the pathologic differences of the hemopoietic organs in each condition. It was our impression when we began this study that infiltration of the gums was more common in acute monocytic leukemia than in other forms of acute leukemia. As Dr Isaacs stated, this feature has been emphasized by many clinicians. We were therefore somewhat surprised to find that in our series lesions of the gums were no more frequent in monocytic leukemia than in myelogenous and other types of leukemia. As far as a comparison of the size of organs is concerned, in the Schilling group the liver was not palpable in any case, but enlargement of the spleen was demonstrable in all four cases and slight enlargement of the lymph nodes was noted in half of them. In the Naegeli group definite but in most cases slight enlargement of the lymph nodes was found in all but two cases. Enlargement of the spleen was demonstrable in fifteen, and enlargement of the liver was noted in thirteen of the twenty cases. Dr Isaacs stated that azure granules are observed only in monoblasts. We have seen azure granulations in the cytoplasm of stem cells in the Naegeli type of monocytic leukemia (monoblasts of many authors). They are common in genuine myeloblasts, as Naegeli, Pappenheim and others demonstrated many years ago, and frequently are seen in these cells in cases of myelogenous leukemia. In myelogenous leukemia one or several cellular lineages may be affected. For example, there have been many reports in the literature of eosinophilic leukemia. There are also cases on record of neutrophilic, basophilic and megakaryocytic leukemia. In each instance a single type of cell is involved primarily. In many of these cases, however, there has been a picture characteristic of chronic myelogenous leukemia during later stages of the disease. In the usual case of chronic myelogenous leukemia the majority if not all types of myeloid elements are involved in the leukemic process (panmyelosis). It is our opinion that the eosinophilic, basophilic and megakaryocytic types of leukemia are variant forms of myelogenous leukemia. The monocyte likewise may be primarily affected being derived from the myeloblast. We have attempted to show that cases in which this occurs differ hematologically and pathologically from cases of leukemic reticulo endotheliosis and that they should be classified as instances of a form of myelogenous leukemia.

### Bone Marrow in the Active Phase of Essential Thrombopenic Purpura

DR LOUIS R LIMARZI and EMIL M SCHLEICHER, M.S., Chicago Although essential thrombopenic purpura has been extensively studied, little attention has been paid to the bone marrow. In our studies of this disease during the active phase (four cases) the bone marrow showed a megakaryocytic hyperplasia with the presence of many young forms (promegakaryocytes). At this time the peripheral blood shows a reduction in number and an abnormality in size of the platelets. These characteristics of the bone marrow persist through remissions induced by blood transfusion, even though the peripheral blood has shown a moderate increase in the number of platelets. After splenectomy the bone marrow approaches normal with an increase in the platelets in the peripheral blood and a cessation of bleeding. In one patient whose episodes of bleeding were reduced but not abolished after splenectomy, the bone marrow still shows megakaryocytic hyperplasia with immature forms. Studies of bone marrow make possible an accurate differentiation of essential thrombopenic purpura from other inaccurately diagnosed hemorrhagic states (aleukemic myelosis, aplastic anemia and toxic purpura).

#### DISCUSSION

DR FRANK H BETHELL, Ann Arbor, Mich I have been performing sternal aspiration before deciding on splenectomy in cases of thrombopenic purpura. I agree with the authors that the procedure is of diagnostic value but I do not think that, for practical purposes, it is necessary to carry out such an involved technic as they have described. I aspirate a small amount of material from the sternum and make cover slip films at the bedside without the use of an anticoagulant. These reveal the characteristic increase in megakaryocytes in patients suitable for splenectomy.

DR LOUIS R LIMARZI, Chicago In our first studies of bone marrow we followed the usual procedure in obtaining marrow. The advantage of the method we described is that sinusoidal blood and fat are separated from the bone marrow cells. In other words, one obtains a concentration of marrow cells. It also offers a method of studying gross quantitative changes that take place in diseases like pernicious anemia or microcytic hypochromic anemia before and after the institution of therapy. This method of studying bone marrow has been followed in 600 patients as young as 6 weeks and as old as 80 years.

### A Specific Cell in the Peripheral Blood, Characteristic of Liver Disease

DR RAPHAEL ISAACS, Ann Arbor, Mich Characteristic of hepatic disease (cirrhosis, chronic passive congestion hepatitis, secondary hepatic disturbance in obstructive jaundice and cholelithiasis, leukemia) is the appearance in the blood stream of a specific cell which may constitute from 1 to 15 per cent of the leukocytes. The cells have an irregular wavy margin, with pseudopodia-like projections in the older forms. The average size varies from 15 by 13 to 18 by 18 microns with an oval nucleus averaging 12 by 9 microns. The cytoplasm stains a sky blue and has a foamy structure like that of a monocyte but the minute red staining granules of the latter are absent. A few large red-staining granules may be present. The tips of the pseudopods are hyaline. The chromatin in the nucleus is coarse with a heavy reticulum but is frequently so dense that but little detail of structure can be seen. There is no discrete nuclear membrane. There is no perinuclear clear zone, as in lymphocytes. With brilliant cresyl blue applied while the cells are wet and counterstaining with Wright's stain when dry, the cresyl blue granulation is in heavy masses near the nucleus and in finer particles near the periphery. Many of the cells with this stain show a clear pink-staining hyaline ectoplasm. The cells appear in the peripheral circulation in experimental liver poisoning in animals.

### The Clotting Time of Hemophilic Blood

DR ARMAND J QUICK, Milwaukee If thromboplastin is added hemophilic blood will coagulate as rapidly as normal blood, which indicates that a deficiency of thromboplastin is the

probable cause of the defective clotting. Furthermore, when oxalated hemophilic blood is centrifuged at a high speed the plasma on recalcification will coagulate much more slowly than if the plasma is obtained by a low rate of centrifugation. The coagulation of plasma from normal blood is only slightly influenced by the speed of centrifugation. This suggests that the platelets in hemophilia are more resistant to lysis and are removed by rapid centrifuging, thus leaving the plasma poor in thromboplastin. When oxalated hemophilic plasma is allowed to stand, its coagulation time when recalcified will become progressively shorter and will approach normal. These observations make it seem probable that the cause of the prolonged clotting time in hemophilia is the slow liberation of thromboplastin from platelets rather than the absence of any factor essential for coagulation.

#### DISCUSSION

DR CARROLL F BIRCH, Chicago As Dr Quick says, the important question is Why do the platelets not break up? One group of authors believes that the platelets have an actual increase in mechanical resistance, while another group holds that the platelets are normal although placed in an abnormal environment, hemophilic plasma. The latter group bases its evidence on the fact that hemophilic platelets behave normally when placed in normal plasma, they agglutinate and rupture within the average time.

### Leukothrombopenia with Increased Capillary Permeability

DRS FREDERICK W MADISON and THEODORE L SQUIPP, Milwaukee We have observed three adults with severe leukopenia, thrombopenia and strongly positive Rumpel-Leeds phenomena. The presenting complaints were extensive suppurative lesions in two and pathologic bleeding in one. In each, recovery from clinical symptoms occurred, but the two with pyogenic lesions thus far have made only partial hematologic recovery. Drug origin was ruled out in each. The erythrocyte count was not significantly involved in any case and responded to ordinary therapeutic procedures. In each instance the leukocyte and thrombocyte counts and the abnormal capillary permeability failed to respond to all medication except the use of epinephrine in one. We believe the leukothrombopenia present in these three patients is a definite clinical syndrome representing another manifestation of the selective, reversible inhibition of bone marrow seen in agranulocytic angina and in some cases of thrombopenic purpura. One of the three patients was found sensitive to milk and made prompt symptomatic and hematologic recovery under allergic control alone. In our opinion it is important to differentiate leukothrombopenia from typical agranulocytic angina and from leukopenic leukemia because of the difference in the clinical course, prognosis and therapeutic management.

### Oral and Intramuscular Administration of Vitamin K in Hemorrhagic Diathesis of Obstructive Jaundice

DRS HUGH R BUTT and ALBERT M SWELL and ARNOLD E OSTERBERG, PH.D., Rochester, Minn. The effect of concentrates of vitamin K prepared from various sources and administered orally and intramuscularly has been studied with reference to the qualitative and quantitative level of prothrombin during the preoperative and postoperative course in cases of various types of obstructive jaundice. A rough inverse relation between prothrombin coagulation time and quantitative prothrombin levels can be demonstrated. The intramuscular administration of the vitamin, while effective in K-avitaminous chicks, is considerably less useful in the human subject than is the oral administration of the preparation. A fall in quantitative prothrombin has been demonstrated postoperatively in a number of cases, a fact which emphasizes the necessity for careful observation.

#### DISCUSSION

DR EMORY D WARNER, Iowa City I should like to ask the authors first what, in their experience, is the level for prothrombin below which the patient is likely to bleed and second what if any correlation they have been able to work out between the extent of the decrease in prothrombin and the

duration and the intensity of the jaundice I have had three cases in which the prothrombin was at a low level and in which I got no prothrombin response by feeding vitamin K concentrate. The patients had advanced hepatic damage in the form of biliary cirrhosis. I felt that the hepatic damage accounted for the failure to respond to vitamin K therapy. It has been shown that hepatic damage will cause lowering of the prothrombin content of the plasma—almost to the vanishing point if the damage is extreme, as in chloroform poisoning in dogs. It is to be expected that in patients with extreme hepatic damage a response to vitamin K therapy cannot be obtained because the injured liver is incapable of producing prothrombin.

DR E. L. TUOHY, Duluth, Minn. Does the test for prothrombin furnish some index of hepatic capacity or function? Through the courtesy of Drs. Butt and Snell I had the opportunity to test out this material, with extremely favorable results, in a patient with carcinoma of the head of the pancreas, with painless, rapidly developing jaundice and a tendency to bleed. I gave it both preoperatively and postoperatively, and the response was exactly as the authors have shown. I should like to ask further if with this method of controlling jaundice there is any further need of attempting to rely to any degree on the administration of calcium, which formerly seems to have given the surgeons considerable comfort.

DR M. A. BLANKENHORN, Cincinnati. Is the plan of treatment the same when the bile is returned to the intestine at operation by anastomosis of the gallbladder as when the bile continues to be excluded from the intestine?

DR HEINRICH NECHELES, Chicago. Did these jaundiced patients with normal prothrombin time who did not receive any treatment with bile salts, blood transfusions or vitamin K bleed nevertheless?

DR RUSSELL M. WILDER, Rochester, Minn. Vitamin K occurs in many foods, so deficiency of it in diets is extraordinary. I should like to ask the authors to add a word about the effect of giving bile alone without vitamin K in these cases with diminished lengthening of the prothrombin time.

DR ARMAND J. QUICK, Milwaukee. This report indicates that clinical study of the problem has gone much further and has been much more successful than the laboratory study. The determination of prothrombin is at best a difficult matter. I fail to understand why there should be a difference in the results of the two methods used, the prothrombin time and the method developed by Dr. Smith and his co-workers. It means that there is still a great deal to be known about prothrombin. I might say that many of these jaundiced patients have slightly antithrombic plasma—in other words, it inhibits the action of thrombin, which might account for a more prolonged prothrombin time than can be accounted for by the actual decrease in prothrombin. If the plasma is highly concentrated, coagulation will be delayed. I just want to point out that the problem is still open as far as experimental work is concerned.

DR HUGH R. BUTT, Rochester, Minn. Warner, Brinkhous and Smith of the University of Iowa have reported that, in dogs with a quantitative level of prothrombin below 20 per cent, bleeding usually occurs. In man, however, the critical level of prothrombin at which bleeding occurs seems to be much higher. We have seen bleeding occur in man with a quantitative level of prothrombin as high as 40 or 50 per cent. I know of no theoretical explanation for this phenomenon, but Dr. Smith also feels that perhaps the critical level of prothrombin at which bleeding occurs for some reason is higher than that of dogs. We have noted some similarity between the elevation of the bilirubin content of the serum and the elevation of the prothrombin clotting time. It is well known that the hemorrhagic diathesis in patients with jaundice occurs most often when no bile is able to enter the intestinal tract. Certain groups of patients seem to bleed more frequently than others, and the frequent tendency to bleed is likely to occur from the following causes in order: (1) anatomic obstruction, such as occurs in carcinoma of the head of the pancreas or biliary ducts, (2) stricture of the biliary ducts, (3) complete external biliary fistula, (4) stone in the biliary duct and (5) diffuse hepatitis. In such cases we have often noted that as the bilirubin content rises the

level of prothrombin in the circulating blood decreases. I was interested to hear Dr. Warner say that he had observed three patients who did not respond to the administration of vitamin K and bile salts. No doubt as more cases are observed all physicians will have a similar experience. The condition perhaps represents an irreversible reaction such as can be observed in many other diseases due to vitamin deficiency.

In reply to Dr. Tuohy, the use of the level of prothrombin as an indication of hepatic function has been fairly well established by the work of Warner, Brinkhous and Smith. By injuring the liver of dogs with chloroform, they have shown that the level of prothrombin is decreased. From their studies they have suggested that the liver perhaps plays a major role in either the fabrication or the activation of the substance called prothrombin. Calcium chloride formerly was believed, and still is by some physicians, to be useful in the treatment of the hemorrhagic diathesis in patients with jaundice, and I believe that it has been well demonstrated by Walters and others to be of distinct benefit. However, the results of experimental research on this problem do not coincide with those of clinical experience. It has been rather definitely shown that the amount of calcium in any of its forms is not appreciably altered in patients with jaundice. Nevertheless, in spite of these theoretical data I do not see any harm in giving calcium, and certainly, since the problem of bleeding is still far from settled, it would seem that an excess of any material necessary for blood clotting might be of some benefit.

Dr. Blankenhorn has asked about the importance of reestablishing the flow of bile into the intestinal tract and Dr. Wilder wishes a more detailed explanation of the value of bile salts. The use of bile salts is based on the fact that in hepatic injury from any cause, and particularly when there is obstruction to the outflow of bile, the quantity and quality of bile salts entering the intestinal tract are poor. It has been well established that the presence of bile salts is necessary for proper absorption of fat-soluble materials. It is assumed that the substance called vitamin K comprises one or more fat-soluble substances, and for this reason bile salts are given to aid in better utilization of this material. Obviously, the first thing of importance is to reestablish the normal flow of bile into the intestinal tract. However, even after this is accomplished, the amount and quality of bile salts entering the intestine is poor. For this reason, we feel that the supplementary use of animal bile salts is important. It is true that if a patient is eating a diet which contains adequate amounts of vitamin K, provided he has only a mild degree of prothrombin deficiency, bile salts alone seem to be sufficient to maintain a proper level of prothrombin. However, if the prothrombin level is greatly decreased, bile salts alone have not proved as effective as vitamin K and bile salts administered together. We have not seen bleeding in patients who had a normal prothrombin clotting time. No doubt, as I have mentioned before, it can occur, since one cannot accurately predict from a single determination of prothrombin clotting time just what is the quantitative level of prothrombin in the circulating blood. As I have just demonstrated, in the patient with a stricture of the common duct the prothrombin clotting time was thirty seconds, while the quantitative level of prothrombin was 38 per cent of normal.

I agree with Dr. Quick that it is difficult to explain just why the quantitative measurement of prothrombin developed by Warner, Brinkhous and Smith does not check more closely than it does with the measurement of prothrombin clotting time developed by Dr. Quick. It seems to me that this discrepancy probably can be explained by the facts: first that both methods are indirect measurements of the substance called prothrombin and second that little is known about the substance designated as prothrombin. It is true that it is thought to be a protein, but little is known of its physical or chemical nature, and until these facts are known the question which Dr. Quick has raised must remain unanswered. We do feel that the methods of measuring prothrombin developed by the two groups of workers are good. The method developed by Quick seems to be better adapted for use in the average clinical laboratory. However, for detailed research in this problem, the quantitative method developed by Warner, Brinkhous and Smith is invaluable.

(To be continued)

## Current Medical Literature

### AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1928 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (\*) are abstracted below.

- Pressor Effect of Amphetamine (Benzdrine) on Normal Hypotensive and Hypertensive Patients W W Dyer Philadelphia—p 103

**Hydroxyethylapocupreine for Pneumonia**—MacLachlan and his collaborators gave hydroxyethylapocupreine dihydrochloride to 149 patients with pneumococcal pneumonia. The substance was taken orally in capsule form, 15 grains (1 Gm) every three hours day and night for from three to five days. In some cases it produced nausea and occasionally vomiting. However, in only a few cases was it necessary to discontinue the drug for this reason. For intravenous use a monohydrochloride solution is given, each 50 cc containing 15 grains and this is injected into the vein every three hours. The intravenous solution is given slowly in from seven to ten minutes. No patient less than 15 years of age has been treated with this substance. During the last year, of the authors' 149 chemically treated patients pneumococcal empyema developed in two, with surgical drainage and recovery. The mortality figure in pneumococcal pneumonia in adults during the last year has been greatly reduced in those patients who received hydroxyethylapocupreine. A comparison of the mortality figures of the chemically treated cases, which were smaller in number, with the serum-treated cases in Pittsburgh for the same types of pneumonia during the same period of time, shows almost identical results. Hydroxyethylapocupreine in this series has shown no evidence of disturbing vision.

**Incidence of Trichinella Spiralis in Man**—Pote gives the results of examining muscular tissue for trichinella larvae tissue from 1,060 unselected necropsies at Barnes and St. Louis City hospitals. All the subjects were more than 15 years of age and had died during hospitalization from some disease other than trichiniasis. Of these necropsies, on the bodies of individuals never suspected of having trichiniasis during life, 163

(15 37 per cent) showed the presence of trichinella larvae in the muscles. The parasites were apparently dead in 95 per cent of the cases. In two subjects, one 17 and the other 19 years of age, the trichinellae were completely calcified. On the other hand, in some cases the parasites moved vigorously and often continued to show signs of life for from one to six days after the muscle had been removed. The presence of live parasites was also demonstrated by feeding infested muscle to white rats and recovering the larval forms at the end of forty days. By these means viable parasites were shown in 5 per cent of the positive cases. The occupation of the infested subjects was determined but no significant association with any line of work was apparent. In 1 500 hog carcasses examined for trichinella, 0 8 per cent were found to be infested, which gives rise to the question whether man is getting all of his trichinella infestation from pork. It may be concluded that man's infestation comes from pork derived from the small packing plants which are not supervised by meat inspection services. It is to be noted that the infestations that occur sporadically are from pork from the establishments not under federal inspection. The author concludes that *Trichinella spiralis* infestation of man is not a serious lethal factor in Missouri, since in the 163 instances of infestation it was not held to have contributed to the actual cause of death.

**Urea Clearance After Hyperpyrexia in Rheumatic Patients**—Farr and Moen performed urea clearance tests on seven rheumatic patients before, during and after artificially induced hyperpyrexia. Of these seven patients two had rheumatic fever, three had subacute or chronic infectious arthritis, one had gonococcal arthritis and one had dermatomyositis. The average urea clearance during the period when the temperature was rising was 61 7 per cent of normal and during the period when the temperature was at a maximum the clearance averaged 75 per cent of normal. In two instances a severe oliguria resulted from the treatment, and these patients were able to void only after twelve hours. For the entire group the average control clearance was 105 per cent when the patients were afebrile. The data indicate that dehydration should be avoided during fever therapy.

**Persistent Diabetes After Pituitary Extract**—Dohan and Lukens confirm the work of Young, who has recently described the production in dogs of diabetes, which continued for months after the cessation of intraperitoneal injections of increasingly larger doses of a carefully prepared extract of the anterior pituitary gland, of Campbell and Best, who have had a similar experience, and of Evans, who reported the persistence of diabetes in two dogs after approximately nine months of treatment with a growth hormone preparation. The present report adds metabolic studies to illustrate the character of the diabetes so induced. While the intensity of the diabetes varied, the metabolic behavior of the animals was similar to that of partially depancreatized dogs. Histologic evidence also indicates damage to the islands of Langerhans.

- Ectopia Lentis Pathologic and Clinical Study C C Clarke New Haven Conn—p 124

**Ocular Manifestations in Brucellosis**—Green believes that since ocular manifestations occur in brucellosis more ophthalmologists, when confronted with a case in which the etiology is not determined, should take advantage of the opportunity to determine by laboratory methods the presence or absence of past or present infection with *Brucella*. Most ocular lesions occurring in the course of brucellosis do not destroy the integrity of the globe. Hence enucleation is not imperative. This fact explains the lack of any pathologic examination of a human eye that has been affected with brucellosis. Evidence is accumulating that some ocular maladies heretofore ascribed to other origins may be caused by brucellosis. The external ocular muscles, the cornea, the uveal tract, the retina and the optic nerve have all proved vulnerable. Almost every physician has been thwarted in his efforts to establish the cause of a chronic uveitis. The ophthalmologist should include in his list of possible etiologic factors a disease that is widespread and one that has been proved capable of affecting almost every tissue of the body (brucellosis).

**Chemoprophylaxis for Polymyositis**—According to Ashley the experimental work of Armstrong Schultz and their collaborators offered the first definite hope of controlling infantile paralysis by the nasal instillation of chemicals. Up to this time immune serums and vaccines failed to protect monkeys against the inoculation of the virus. Their work paved the way for trials of chemicals in preventing the disease in human

beings. Certain chemicals applied to the olfactory tracts of monkeys have rendered the animals resistant to infection with the virus after repeated intranasal instillation. Fifty or sixty chemicals have been tested for this protective property, and while zinc sulfate is not toxic and seems to be the most effective it causes certain irritating and unpleasant symptoms and is not the ideal solution. Anosmia which develops after chemical treatment is probably an evidence of the completeness of the nerve blocking and an indication of the protection. The duration of the anosmia when zinc sulfate is used varies greatly in different persons, but apparently the sense of smell always returns. In this type of treatment is practical, the effectiveness of the protection will depend on the thoroughness of the nerve blocking. Functional tests for the return of the sense of smell should be the guide for further chemical application. While the experience during human epidemics has so far failed to show definite protection, further trials are indicated since previous methods of application have been faulty. If this treatment proves effective in man it will still not be an ideal prophylactic, as the protection afforded is short and as it fails to produce any immunity in the individual to the virus. Nevertheless it is the only method available which promises any hope of actually combating the disease.

**Throat Irritation from Cigarette Smoke**—Ballenger did not find, after a careful objective examination of 102 cigarette smokers, any significant difference in the irritation of the mucosa of the nose or throat from smoking cigarettes moistened with glycerin those moistened with diethylene glycol or those with no hygroscopic agent. The subjective symptoms or sensations of irritation, when present, were not marked enough in respect to distribution, character or degree to justify definite conclusions. Lymphoid hyperplasia of the pharynx does not appear to have any relation to the number of cigarettes smoked.

- Some Aspects of Intermediary Metabolism of the Steroid Hormone G F Marrian Toronto—p 27
- \*Infectious Mononucleosis J R Paul New Haven Conn—p 43

**Infectious Mononucleosis**—Paul believes that there are few diseases in which one is so fortunate as to have three definite diagnostic aids (clinical picture, blood counts and serologic test) and yet, in spite of them, the disease probably often escapes recognition. Sometimes the clinical symptoms are mild there seems to be such a thing as "walking infectious mononucleosis" and these and other cases may easily escape recognition if differential blood counts are not done. The classic physical signs of the disease are well known and do not require repetition but the author mentions three clinical features which are not common but are striking when they occur. 1 Ocular symptoms probably occur more frequently than one would be led to believe. In their early stages they are characterized by pain in the eyes or pain back of the eyes which regresses during the second week but leaves the patient with puffy eyelids. 2 A papulomacular rash is an irregular symptom but one which has been emphasized by Tidy. The eruption is diffuse or patchy and generally limited to the trunk. It is difficult to describe it by any other term than morbilliform, in two of the author's cases it was classified by the attending physician as a "drug

rash. It may be preceded or accompanied by an enanthem consisting of petechiae on the soft palate. Jaundice is another manifestation present in the second or third week of the disease. It is often definite and striking. A recent report from Sweden emphasizes its importance. Infectious mononucleosis is a benign condition which is self limiting in two or three weeks. However, it may be a long time (perhaps six months) before the glands return to normal size and a long time before the patient feels well again. So prominent is this postfebrile depression that in severe cases it seems to be part of the disease.

The Management of Glaucoma T I McKee Keokuk—p 14  
Lymphocytic Choriomeningitis in Iowa W H Presnell Charlotte—p 18

**Significance of Changes in Leukocytes**—Sturgis points out that a careful study of the circulating leukocytes yields valuable information concerning the diagnosis and prognosis of certain diseases, especially when this information is considered with other clinical data. In general, such knowledge is derived from a consideration of the number of leukocytes, the differential leukocyte count, the character of the nucleus as an indication of the maturity of the cell and certain abnormal changes which occur in the cytoplasm. Too much dependence should not be placed on single isolated observations, because repeated tests are desirable as a check on the accuracy of the estimations and because frequent determinations furnish data on which a curve may be constructed and this serves as a valuable indication concerning the general trend of any disease process. The author discusses the changes in the polymorphonuclear leukocytes in infection, infectious mononucleosis, agranulocytic anemia, and the leukemias.

**Basophilic Aggregation Test in Cement Workers**—Holden and Ralston found a significant increase in the basophilic aggregation count in sixty-three workmen exposed for an average of more than eleven years to limestone, shale and cement dust. No pathologic change in the cells suggestive of plumbism was found. The average basophilic aggregation count of seventy-three fellow workmen who were not exposed to dust was approximately the same as the average of all the workmen employed in the dusty areas. No evidence was found to indicate that the increased stippled cell counts obtained by Lehmann from the Thuringian cement workers is paralleled by a similar increase in basophilic aggregation counts made on cement workers in the United States.

**Hydration Studies in Epilepsy**—The Ziskinds and Bolton draw certain deductions relative to dehydration therapy in epilepsy from the study of sixteen epileptic patients and nine normal subjects who drank, after an overnight fast 7000 cc of tap water at a uniform rate of 1,000 cc each half hour. Body weight, urinary output and specific gravity were recorded at intervals of thirty minutes. Convulsions followed hydration in half of the epileptic patients. There were no convulsions in the nine normal subjects. Blood dilution and water retention were greater in the epileptic than in the nonepileptic subjects. This observation, if substantiated may have important bearing on the question of increased cell permeability in epilepsy. Blood dilution and water retention were greater in epileptic patients having seizures subsequent to hydration than in those not so affected. Although excessive amounts of water were a positive factor in precipitating seizures, average amounts did not have this effect. The results cast doubt on the efficacy of dehydration in controlling convulsions.

**Plasma Fibrinogen Response in Man**—Ham and Curtis investigated the effect of nutritional deficiency and of protein feeding on the fibrinogen level in man and compared the fibrinogen response to artificial fever. The plasma fibrinogen response is compared to the variation in serum proteins, leukocytes and body temperature. Their conclusions are that 1 The plasma fibrinogen concentration in normal human subjects is relatively constant for any one individual and is not significantly influenced by the conditions of fasting, ingestion of food, rest and short violent exercise. The limits of concentration observed for normal adult men and women are from 190 to 330 mg per hundred cubic centimeters of plasma, with an average level of approximately 250 mg. 2 In uncomplicated and untreated cases of pernicious anemia in which dietary protein has been inadequate, the fibrinogen concentrations vary from below normal to normal levels with a lower average concentration than that of healthy subjects. 3 Nutritional deficiency in pernicious anemia, in scurvy and in pellagra does not prevent an increase of fibrinogen above normal in the presence of infection. 4 In normal subjects the daily ingestion of animal protein produces a moderate fibrinogen response, usually within normal limits. 5 Remission from pernicious anemia does not result in an increase of plasma fibrinogen when the diet is deficient in protein but is accompanied by an increase of fibrinogen to normal when the diet contains 50 Gm of protein daily. 6 Fever induced by high environmental tem-

perature causes either no elevation or only slight and irregular elevation of plasma fibrinogen, whereas the intravenous injection of typhoid vaccine causes both fever and a significant and prolonged elevation of the fibrinogen level. Therefore fever probably is not the only cause of the abnormally increased concentrations of fibrinogen observed in many febrile diseases. 7 In infectious disease the fibrinogen response may be independent of the temperature and the leukocyte changes and may occur despite a failure of the leukocyte response. 8 A failure of fibrinogen to increase above normal in instances of severe infection may be a poor prognostic sign and may suggest the presence of significant hepatic damage even though clinical signs of disease of the liver are lacking.

Nodular Cirrhosis of Liver Case Report J C Eagan Madison—p 28

**Deficiency Disorders in Heart Disease**—Niehaus and Wright consider the influence of various nutritional and deficiency states in connection with heart disease. The chief complaints of persons with cardiac disorders are referable to the gastrointestinal tract, at least sharing equal mention with the respiratory system. At present vitamin B<sub>1</sub> appears to be the only one of the vitamins having important cardiovascular influence. With regard to the heart it seems significant that the myocardium is richly supplied with vitamin B<sub>1</sub>, being exceeded only by the liver and kidneys (Cowgill). This would seem to indicate an increased need rather than a storage place. Jones and Sure reported marked improvement in heart disease in patients receiving daily from 1,500 to 2,200 units of vitamin B. Their analysis, however, is not entirely convincing. Obesity has long been recognized as a handicap to the cardiovascular system. The very common occurrence of breathlessness with overweight is evidence that this condition imposes a circulatory load which is met with some difficulty. In addition to the local deleterious effect of deposition of fat around and within the wall of the heart, fat deposits in the rest of the body demand extra cardiac effort. While many other etiologic factors causing heart disease are obscure and difficult to influence, the factor of obesity offers a method by which these diseases may be prevented or, if present, more favorably influenced. The gratifying fall of blood pressure with weight reduction is a common experience. Undernutrition may be a factor in cardiovascular disease. This, unless very marked, usually does not have an important part in the cause of heart disease. Only with extreme

wasting of the skeletal muscles is the weight of the heart reduced from 20 to 50 per cent. But more often it is a factor in heart disease due to other etiologic agents, such as is manifested in cardiac cachexia. This disorder has been considered a toxemia but is more probably a deficiency state. This is frequently attended by anemia and hypoproteinemia. These factors prevent proper nourishment of the myocardium as well as of the rest of the body. A low intake of proteins or protein sparing foods as carbohydrates may be factors in impoverishing the blood. Besides this a deficient intake of vitamins B and C may be further factors. Vitamin C deficiency may result in capillary damage and permit easy exit of the blood from the capillaries. Anemia also prevents adequate nutrition of the myocardium. Impoverished blood may not supply sufficient oxygen to the heart, which may result in an anoxemia manifested by a typical anginal syndrome. This may occur in anemia, particularly in the presence of a defective coronary vascular system.

**Type III Pneumococcus Pneumonia**—Lawrence used sulapyridine in the treatment of two cases of type III pneumococcus pneumonia. Both patients recovered and the crisis occurred with rapid abatement of symptoms. Recovery was uneventful. Both patients were men more than 65 years of age, both were addicted to alcohol, and hypertension, auricular fibrillation and chronic bronchial asthma complicated the picture. Crisis occurred after only a small quantity (respectively 4 and 10 Gm) of the drug had been administered, possibly demonstrating the direct action of the drug on the invading organism regardless of the concentration of the drug in the blood (the initial dose was respectively 1 and 2 Gm). The only untoward symptoms produced by the drug were nausea, hiccuping and mild cyanosis, all of which rapidly cleared on cessation of the drug. The toxicity of the drug appears to be much less than that of sulfanilamide. Bacteriologically, in the reported cases, the main action of the drug is first to cause the loss of type specificity of the pneumococcus, which is then followed by complete decapsulation of the organism and finally by its inability to grow either on artificial mediums or in the mouse's peritoneum. It seems that there is a definite bacteriostatic action since improvement is observed so early in the disease. On mouse passage the reverse process is observed first the reappearance of the capsule and second the reestablishment of type specificity. There was no demonstrable change in the type of the original organism in spite of the complete decapsulation and mouse passage.

 \*Sinusitis in Children A B Miller Pittsburgh—p 399  
 Edema Its Differentiation and Treatment R R Snowden, Pittsburgh—p 403

**Sinusitis in Children**—Miller declares that every acute cold is potentially an acute sinusitis. In children the acute exanthems, especially measles and scarlet fever, are often accompanied by severe acute sinusitis, which later leads to chronic involvement of the sinuses. Silverman reports an x-ray study of 300 cases of scarlet fever, 91 per cent of which showed definite sinusitis during the disease. The child who is undernourished, who has poor hygienic surroundings or an inadequate diet or who has some underlying constitutional condition is more apt to develop acute sinusitis just as he is more likely to develop chronic sinusitis. Anything which causes mechanical obstruction to normal nasal aeration and ventilation is another predisposing cause. The exciting causes are acute catarrhal fevers, acute exanthems, swimming and diving. Home treatment as a rule is sufficient in acute sinusitis and usually falls to the lot of the pediatrician or family practitioner. Adequate ventilation and drainage are important and should be accomplished by frequent use of astringent drops or sprays. Frequent use of inert liquid petrolatum drops in young children is contraindicated because of the danger of producing pneumonia. Only in the presence of some grave complication should any surgical procedure be undertaken in acute sinusitis and it should be as conservative as possible. The simple drainage of a subperiosteal collection of pus by incision through the periosteum is usually adequate. The ethmoidal labyrinth should never be attacked by the intranasal route in childhood because the possibility of meningitis is too grave. Osteomyelitis requires extensive surgical removal of bone. Unfortunately too many cases of acute sinusitis pass insidiously to the subacute and chronic state, the patients being discharged as cured. The prognosis of chronic sinusitis in children is better than in adults provided proper treatment is given. Treatment should be persisted in over a considerable period and a child should be observed periodically for several years before he is discharged as cured of chronic sinusitis.

 \*Nonindustrial Injuries Among Male and Female Industrial Employees H P Brinton—p 6

**Nonindustrial Injuries**—Brinton reviews the data on nonindustrial injuries and sickness causing disability for eight consecutive days or longer reported to the United States Public Health Service by industrial sick benefit organizations. Examination of these reports shows a small but consistent excess in the rate of nonindustrial injuries among female industrial employees for all companies and for eleven companies which reported to the United States Public Health Service for the entire period 1925 through 1937. For one company an analysis of all nonindustrial injuries which lasted eight days or longer revealed that the difference between the male and female rates was largely due to a relative excess among women of injuries to the lower extremities and injuries to multiple parts of the body. The frequency of injuries was shown to vary according

to age as well as to sex. The injuries were found to be less serious among women than among men, while the average number of days lost per person was slightly greater for the former. When a company which reported disabilities lasting from one to seven days inclusive was selected, the relative excess of women became considerably greater. It appears from this study that, for the companies reporting, women were absent from work more often and for a longer time because of nonindustrial injuries than were men. This does not necessarily indicate that women are more prone to such injuries, as other factors, such as a different psychologic attitude toward injuries or a different attitude toward regularity of attendance at work, may play a part. The type of injury was classified in 86.6 per cent of the male injuries and in 85.4 per cent of the female injuries. Assuming that the unknown injuries are evenly distributed, it would appear that women had relatively fewer fractures than men but more sprains, cuts, bruises and burns. The proportion that fractures bear to all types of injury increased slightly with advancing age. There was an apparent tendency for the difference between the male and female percentages to be less in the older age period with respect to sprains and more with respect to burns, cuts and bruises.

**Reduction of Pneumonia Mortality by Serum Therapy**—Head points out that the need for all possible speed in the bacteriologic diagnosis and serum treatment of pneumonia is clearly shown by the lower mortality when this treatment is begun early after onset. The sooner serum is given after onset, the lower will the mortality be. Pneumonia is a medical emergency just as acute appendicitis is a surgical emergency. The physician who waits for dulness, bronchial breathing and other signs of consolidation to appear before making a diagnosis of pneumonia has allowed the most propitious time for treatment to pass. The patient who suddenly develops chills, pain in the side, cough with rusty sputum and fever should be considered to have pneumonia until proved otherwise. Failure of a patient to respond to serum after from twelve to eighteen hours calls for a complete bacteriologic restudy of the case, that is, typing of the pneumococcus and a culture of the blood. It has occasionally happened that a patient has received serum of a type corresponding to the organism found in his sputum, without favorable response, and a culture of his blood showed a pneumococcus of a different type.

**Cortical Deafness Without Aphasia.**—Since Henschen (1918) collected sixteen cases of cortical deafness which up to that date had been reported with postmortem examination, Bramwell (1927) and Misch (1928) have each reported a further case. Now Clark and Russell present a case unlike other recorded cases in that the lesions were both subcortical and were so limited that there was no associated aphasia.

**Myelinopathy in Carbon Monoxide Poisoning.**—Hsu and Cheng made postmortem examinations of three cases of carbon monoxide poisoning. One of these showed typical bilateral hemorrhagic softening in the globus pallidus with no significant changes in the white matter and two presented diffuse changes in the deeper cerebral white substance. Clinically these two cases belong to the so called relapsing type that is, secondary changes appeared after recovery from the initial disturbances. One of these patients presented symptoms of catatonia and parkinsonism and died four months after the poisoning. In the other patient bronchopneumonia and empyema developed and he died four weeks later. Both brains showed a more or less diffuse degeneration of the white matter with progressive changes of glia cells and patches of demyelination. There was no bilateral softening of the globus pallidus. A direct influence of the poison, or its anoxic effect on the nervous tissue, is emphasized as a prominent pathogenic factor in these cases.

- Rheumatic Headache. J. Cyriaque—p. 1367

**Ulcerative Colitis.**—Wittkower observed, from the psychologic point of view, forty unselected cases of ulcerative colitis. In thirty-seven cases psychologic abnormalities and disorders, far beyond the range of individual differences in the average population, were found to antedate the initial onset of the colitis. A dated clinical and life history, taken independently and verified by relatives, showed that disturbing events in the patient's life had preceded the onset, return and increase of symptoms more often than can be due to chance. Almost all the patients showed character disorders, obvious neuroses or psychoses. Seventeen patients who were overconscientious, overscrupulous, too orderly, most particular in cleanliness, obstinate and the like had obsessions. Twelve, characterized by emotional lability, temper tantrums, childishness, self centeredness and suggestibility, had hysterics. A group of six patients less well defined than the others contained some schizothymes and depressives. Five patients could not be grouped. The precipitating conflict situations, although fairly uniform within the various groups, showed no universally common similarities. If the relative significance of somatic and psychologic factors in the etiology of ulcerative colitis is assessed, little can be said in favor of a primary bacteriologic or dietetic origin. The psychologic factor seems the

most constant cause. The riddle of the etiology of ulcerative colitis is still far from being solved. The psychologic background described is not necessarily the cause of the obscure disorder but it is certainly an important factor in the disease. Many problems in relation to the physical and psychologic aspects of the disorder await discovery. The observations appear to justify an attempt at psychotherapy for selected early cases of ulcerative colitis.

**Sonne Dysentery.**—Trimble and Brothwood report an outbreak of Sonne dysentery due to contaminated milk. It was not found possible to determine the source from which the milk became contaminated. Administrative action was followed by a prompt cessation of the outbreak, except for two "secondary" cases which illustrates that instructions were not carried out faithfully. The outbreak demonstrates the importance of repeated examination of the feces of those infected if secondary cases are not to occur through a person's ignorance of the fact that he is still excreting the organism long after he appears to have recovered. It is particularly important that repeated examinations should be made of the persons actually handling milk and that they should be scrupulous in their personal cleanliness. The milk was supplied to twenty-four households, but only twelve were affected by the outbreak. Eighty-six persons partook of the milk incriminated in the outbreak, but only twenty-one became ill.

**Prevention of Paralytic Ileus.**—In his discussion of the prevention of paralytic ileus, Cairney does not include the ileus due to peritonitis. Prophylaxis at operation (laparotomy) consists principally in the avoidance of every form of unnecessary trauma. In the postoperative prevention of paralytic ileus the author advocates that for the first forty-eight hours the patient be given from one-sixth to one-fourth grain (0.01 to 0.016 Gm.) of morphine as necessary for the relief of pain and restlessness but not more often than every four hours. On the third morning the abdomen should be examined with a stethoscope. If audible peristalsis is present an enema is ordered, and if the result is satisfactory any suitable aperient may be given in just sufficient quantity to ensure a daily action of the bowels. If on the third morning audible peristalsis is absent and distention is commencing, prostigmine and acetylcholine are administered, followed by an enema. In some cases this is all that is necessary, in others the prostigmine and acetylcholine are repeated at intervals as indicated and radiant heat is applied to the abdomen. In these cases the occasional administration of morphine may have to be continued but is generally required only at night to ensure adequate rest. If on the third morning peristalsis is not audible but there is no sign of abdominal distention, the choice lies between delaying the administration of the enema, on the assumption that peristalsis will be in evidence some hours later, and the administration of prostigmine and acetylcholine. In no case is an aperient administered until a satisfactory result has been obtained from an enema. Each patient must be treated individually.

- Lipomas of Cecum R Didier—p 1070
- Late Gastric Ulcer Case N D Hoang—p 1078

## Splenoperivisceral and Spleno-Ulcerous Syndrome—

Caroli and his associates direct attention to two anatomoclinical syndromes which may be associated or occur isolated the splenoperivisceral syndrome and the spleno-ulcerous syndrome. In the splenoperivisceral syndrome the adhesions around the digestive tract coexisting with the splenomegaly may be limited to the duodenal bulb, or in other cases they may extend over the entire abdomen. One of the cases described in this report is of a hitherto unreported instance of association of hepatosplenic cirrhosis of undetermined origin and of ulcer of the duodenum. The fatal digestive hemorrhages which complicated this case seemed to be due to rupture of varices of the cardia. This case raises the question whether the involvement of the peritoneum is not perhaps the cause of the splenomegaly rather than an associated or secondary complication. Regarding the spleno-ulcerous syndrome, the authors say that they do not believe that this syndrome is purely coincidental but that it is probably grafted on the organic and functional alterations of parasplenomegalic gastritis. In one of the cases the muscular hypertrophy of the gastric wall demonstrated clearly what severe changes may be located in the stomach. Without doubt, they explain to a considerable extent the frequent postoperative persistence of hemorrhagic accidents. On the basis of two observations, the authors were able to show that the coexistence of ulcerous complications are of interest in relation not only to the spleen but likewise to the hepatosplenic cirrhoses, which may or may not be of alcoholic origin.

- Pathogenic Consideration of Certain Forms of Schizophrenia in Asthenic and Dysplastic Persons in Connection with Case of Acromeria Tremor of Head and Lactic Secretion M Cahane and Tatiana Cahane—p 942

## Nature of Parkinsonian Tremor—Nyssen and his asso-

ciates say that in the course of previous investigations relative to certain clinical characteristics of parkinsonian tremor and to the influence of certain factors on the amplitude and frequency of this tremor they observed in a considerable number of subjects that the members do not tremble in a synchronous manner. Since this observation was in disagreement with the opinions of other observers, the authors decided to investigate this problem systematically. They studied fifteen patients with paralysis agitans and thirty patients with encephalitic parkinsonism. The tremor was registered by means of the mechanographic method. For a comparison of the frequencies of the tremor in two symmetrical homolateral or crossed members, the registration was always made simultaneously. The differences of the frequencies of two members were expressed in percentages. For instance if, during a period of ten seconds, the right hand registered fifty oscillations and the left hand sixty it was said that the tremor of the left hand is 20 per cent more rapid. To the question whether there is synchronism in parkinsonian tremor the authors reply that among their forty-five patients they detected a single case of relatively stable synchronism between two limbs. This patient presented identical frequencies in the right hand and the right foot. However, a comparison of the frequency of the right members with those of the left members presented the same asynchronism found in the majority of patients. The asynchronism observed in the other forty-four patients varied between 30 and 100 per cent. Further the authors investigated whether the degree of asynchronism differed according to whether the compared members were symmetrical homolateral or crossed. The detected averages do not indicate this but in

some subjects the asynchronism of the tremor was more pronounced in the symmetrical members, in others more in the homolateral or crossed members. The authors intend to continue their studies in order to detect the factors that will explain the asynchronism in parkinsonian tremor.

## Antityphoid-Paratyphoid Vaccines—Chalier and Ledru

maintain that the value of antityphoid-paratyphoid vaccination cannot be denied. When it is administered by the subcutaneous route and in suitable doses it greatly diminishes the morbidity. However, they gained the impression that the different modes of vaccination are not all of the same value. They advise against the oral administration. The lipovaccines confer an immunity of short duration. The ether vaccine of Vincent produces the most reliable and the longest lasting immunity. The attacks of typhoid which developed in spite of this vaccination occurred mostly in subjects who had not been correctly vaccinated, not having received more than two injections. The heated TAB (triple) vaccine, especially when reduced to two injections, seemed less efficacious. Its immunizing power is of shorter duration and allows more refractory cases to persist. During the war and postwar years, typhoid in those vaccinated with ether vaccine was an extreme rarity. Less exceptional is typhoid of those vaccinated with heated triple vaccine, who may develop it as early as one or two years after the vaccination. The ether vaccine often provokes strong reactions, but these may be necessary for the development of a lasting immunity. The question therefore arises whether it might not be advisable to return to this mode of vaccination, with the multiplicity of injections which it requires but at the same time with reward of a reliable and lasting immunity.

47 1740 (Jan 7) 1939

- Sites of Origin of Ovarian Hormones Hyperplasia of Endometrium as Test of Hyperestrinism J Wallart—p 17
- \*Icterus in Diabetic Patients P Ducas and P Uhry—p 19

## Icterus in Diabetic Patients—Ducas and Uhry say that

the concurrence of diabetes and icterus is less frequent than might be supposed. When the two disorders concur in persons over 50, the question arises whether it is merely a coexistence of diseases or a multiple manifestation of a complex diathesis. However, when the association occurs in children or young adults, the various factors that could be incriminated as possible causes of the icterus in old persons, such as alcoholism, lithiasis, malaria, syphilis and chronic intestinal intoxication, have not had time to develop or exert their effects and thus it is especially interesting to study the concurrence of diabetes and icterus in the young. The authors describe several cases of concurrence of diabetes and icterus in young persons. One patient was a man aged 22 who had had diabetes since the age of 14 and who developed a spirochetal icterus which led to an attack of acidosis and to a temporary decrease in the carbohydrate tolerance. Two other patients were boys aged 12 and 13 who had had diabetes for several years. In these cases the icterus was accompanied by hepatomegaly. The authors say that these histories reflect those reported by other authors. They show that the form and evolution of the icterus are little modified by the diabetic condition and that the aspects of icterus vary according to its etiology and are identical with those of nondiabetic persons. The only point which merits especial attention in the diabetic patients with icterus is the existence of an enlargement of the liver. This hepatomegaly may appear before the icterus or simultaneously with it. It may be slightly painful, but as a rule it is accompanied neither by ascites nor by splenomegaly. Generally it is transitory and disappears with the icterus, nevertheless it may persist for a long time after the icterus has already disappeared.

Discussing the significance of this hepatomegaly, the authors show that it probably plays a part in the genesis of the icterus. In conclusion they stress that the icterus of diabetic persons, especially of young diabetic patients, does not have a uniform etiology, that it is comparatively rare and that the prognosis is as variable and as difficult to establish as is the case in non-diabetic persons. Its effect on the diabetes becomes manifest, as a rule, by a transitory aggravation of the diabetic disorder. The diet of these patients must be carefully watched, that is, the intake of fats should not be too high and that of sugars not too restricted.

Clinical Aspects of Infectious Diseases R. Strahelin—p 1

Adequate and Inadequate Nutritional Preparations E. Burgi—p 7

\*Impairment of Heart in Tonsillitis H. W. Hotz—p 10

Meniere's Disease Case R. Guyot—p 12

**Impairment of Heart in Tonsillitis**—Hotz says that during the first part of 1938 tonsillitis assumed epidemic proportions at the medical clinic of the University of Zurich. The contagiousness of the tonsillitis was considerable, several room infections were observed and many of the nursing staff contracted it. Other unusual aspects of this epidemic of tonsillitis were frequent articular symptoms and electrocardiographic changes. It was decided to make electrocardiographic tests on all patients who had had inflammatory disorders of the tonsils, and abnormalities were observed in a surprisingly large number. It is noteworthy that if the occasional rhythmic disturbances are disregarded these electrocardiographically detectable disturbances often fail to cause clinical manifestations. The pathologic aspects of the electrocardiogram are usually transitory, moreover, they generally do not appear during the severest period of the disease but rather after the symptoms of sore throat and fever have already disappeared. As a rule there is no parallelism between the severity of the clinical aspects and the electrocardiographic disturbances, for severe electrocardiographic changes may appear in cases of tonsillitis that are comparatively mild and of short duration, and vice versa. The author cites and illustrates some of the electrocardiographic changes that he observed in acute cases of tonsillitis and says that other investigators observed similar changes during chronic tonsillitis and saw them disappear after tonsillectomy. In the concluding summary the author says that acute tonsillitis leads in a large percentage of cases (according to Otto in 60 per cent) to electrocardiographic changes which are probably the result of transitory, probably toxic, influences on the myocardium and the cardiac conduction system. Occasionally, myocarditic or coronaritic disorders may develop. The author admits that it would be impractical to subject every patient with tonsillitis to electrocardiography, however, he emphasizes that physical exertion should be avoided during the period of convalescence and the patients should be carefully watched. Patients with chronic tonsillitis should be subjected if possible to electrocardiography, and tonsillectomy should be resorted to if pathologic changes are observed.

\*Sign of Pain in Phrenic Nerve in Diseases of Abdominal Organs C. Roncoroni—p 1683

V<sub>1</sub> Antigen of Bacterium Typhi L. Soletta—p 1692

Permeious Anemia of Pretended Known Etiology A. Terzani—p 1721

**Phrenic Nerve in Diseases of Abdominal Organs**—According to Roncoroni a reflex pain in the cervical point of the phrenic nerve (right supraclavicular fossa) is frequent in several diseases of the abdominal organs. It may be spontaneous or induced by palpation over the phrenic nerve on its passage on the anterior scalenus muscle (right supraclavicular fossa). The author investigated the presence of phrenic pain in 130 patients suffering from any of various diseases of the abdominal organs. He found that phrenic pain exists in all cases of diseases of organs in the right side of the abdomen and in pericholecystitis and cholecystitis both with and without calculi. The sign may be positive (presence of phrenic pain) in appendicitis (either acute or chronic), periduodentitis and duodenal ulcer whenever the cystic point is painful and not otherwise. It is negative

(absence of pain) in both the right and the left sides, in gastric ulcer, in gastric cancer, in renal calculi and in pyelonephritis. According to the author the sign is of diagnostic value, showing pathologic conditions of either or both the gallbladder and the perihaptic peritoneum. He believes that pain in the phrenic nerve shows a reaction of irritability of the nerve to a direct involvement of its peritoneal branches in the local inflammatory process. Involvement of the peritoneal phrenic branches in the local pathologic process induces a painful reaction which is transmitted to the upper segments of the nerve.

Hypovitaminosis in Clinical Diseases M. R. Castex and M. Schtenegart—p 2437

\*Alterations of Liver in Erythroblastic Anemia with Jaundice. M. Acuna and A. A. Bonduel—p 2444

Treatment of Achylic Hypochromic Anemia E. S. Mazzei—p 2453

**Liver in Erythroblastic Anemia**—According to Acuna and Bonduel, the liver becomes involved in the course of hemolytic erythroblastic anemia which results from the contact of the structure with hemoglobin from hemolysis. The lesion in the liver permits the passage of direct bilirubin to the blood with consequent development of jaundice with a clinical picture which is similar to that of hemolytic jaundice (Minkowsky-Chauffard's type). The authors made a clinical study and tests for the function of the liver in several children and adolescents who were suffering from erythroblastic anemia with jaundice. They found that the patients have periodic aggravations which are controlled by transfusion. The crisis of the blood is that of intense anemia with presence of a large number of immature erythrocytes and leukocytes. Frequently the blood picture is that of von Jaksch's pseudo-leukemia. The liver is enlarged. Material from the liver which is taken by a biopsy shows various alterations of the structure, especially acute infiltration with pigments derived from hemoglobin. The Kupffer cells of the liver are engorged with transformed hemoglobin. Serial tests for function of the liver show insufficiency, which depends on the intensity and evolution of erythroblastic anemia. It intensifies in the periods of deglobulization and improves during the periods of amelioration of anemia. The elimination of hippuric acid is diminished. Bilirubinemia and galactosuria are increased. Hyperbilirubinemia is indirect early in the development of the disease and direct as the latter progresses. Hunter and Harrison tests for bilirubin in the urine gave positive results. Urobilinuria is increased especially during the periods of deglobulization and in advanced phases of the disease. The authors therefore conclude that erythroblastic anemia with jaundice and congenital splenomegaly hemolytic jaundice (Minkowsky-Chauffard's type) are two different clinical forms of congenital hemolytic jaundice.

**Carbohydrates and Minerals in Pregnancy**—Discussing the carbohydrate metabolism during pregnancy, Albers says that the blood sugar level is generally low during pregnancy. On the basis of a large number of metabolic tests it has been concluded that the glycogen fixation is reduced or that there is a considerable glycogenolysis. However, in spite of the low blood sugar content a tendency toward increased mobilization of the sugar can be demonstrated by means of sugar tolerance tests. The changes in the course of the carbohydrate metabolism are the result of the incretory changes of pregnancy. The anterior lobe of the hypophysis, the thyroid

and the adrenal system promote the contra-insular process. Some forms of glycosuria are not caused by insufficiency of the insular apparatus but rather by hyperfunction of the contra-insular system. The regulation by thecretory system of processes in the intermediate carbohydrate metabolism helps to explain conditions like alimentary and extra-insular glycosuria of pregnancy. The author stresses the importance of the differentiation between true diabetes mellitus and the extra-insular glycosuria of pregnancy. In the extra-insular glycosuria of pregnancy the blood sugar content is not related to the elimination, the sugar tolerance test produces normal results and the elimination of sugar is independent of the carbohydrate intake, moreover, the glycosuria is refractory to insulin therapy. If the examination of the pregnant woman who has glycosuria discloses true diabetes mellitus the customary dietetic and insulin therapy must be instituted, but if the glycosuria is of the extra-insular type treatment is either unnecessary or it is of a type exactly opposite to that of diabetes mellitus, that is, the pregnant woman must be given more carbohydrates than she eliminates so that the balance will be a positive one. During the later periods of pregnancy the glycosuria usually decreases and often disappears entirely. The author shows further that in some hepatic impairments of pregnancy carbohydrate therapy is advisable and that it promises favorable results also in hyperemesis gravidarum, severe dropsy of pregnancy, preeclampsia and eclampsia. In the course of a hyperemesis the urine of the patient should be examined from time to time for the presence of sodium chloride. If on addition to the urine of a 1 per cent solution of silver nitrate there appears a sediment of thick white floccules, hypochloremia is absent, but if the urine remains clear a sodium chloride deficiency of the blood must be suspected and searched for and the rest nitrogen content must be tested. The intravenous administration of sodium chloride increases the salt content of the blood and reduces the rest nitrogen. But although hypochloremia is so far the only disorder curable by mineral therapy the author thinks that the late toxicoses might perhaps be influenced indirectly by minerals.

German Measles a Virus Disease Y Hiro and S Tasaka —p 328

**Atrophies in Nurslings**—According to von Szasz and von Gardos the entire organism, including the cretory glands, are involved in atrophy of nurslings. The symptomatology of the atrophy differs depending on which organ dominates the disease process with its atrophy. The authors observed some cases with symptoms of atrophy of the liver and of the posterior lobe of the hypophysis. After listing the characteristics of the normal liver in nurslings they mention the changes that develop during atrophy and then they discuss the treatment. They show that, in cases of grave atrophy with small liver, the hepatic function can be improved (1) by nourishment with foods that have comparatively high carbohydrate and sodium chloride contents, however, the tolerance must not be exceeded, (2) by the parenteral administration of solutions of sugar and of sugar and salt, (3) by feeding with vegetables that have a high vitamin content, (4) by injecting blood serum (5) by intramuscular injections of liver extract, and (6) by the administration of liver sugar and solution of posterior pituitary. As the size of the liver increases, the general condition and the tolerance improve. The administration of solution of posterior pituitary is indicated (1) in the severe forms of atrophy with polyuria and polydipsia, provided hydrostasis and edema are absent, (2) in Leiner's dermatitis and generalized eczemas, when it should be given in small doses during the erythematous stage until vasoconstriction results and (3) in cases of severe meteorism which result from intestinal paralysis and complicated toxic and septic disorders. However, the administration of solution of posterior pituitary is contraindicated in the forms of atrophy that are accompanied by vasoconstriction and edema.

Clinical Roentgenologic Diagnosis of Cancer of the Cardia of the Stomach S L Kopelman and I L Tager —p 1485

**Early Diagnosis of Gastric Cancer**—According to Bruskin, more than 50 per cent of the patients suffering from cancer of the stomach come to the surgical services or to the oncologic institutes in an advanced inoperable state. The mortality from gastric cancer in Moscow during the years 1929-1931 amounted to 40 per cent of the total mortality from malignant neoplasms. During the years 1926-1934, 250 cases of gastric cancer were treated at the Central Oncologic Institute of Moscow. The distribution according to sex was 60 per cent in men and 40 per cent in women. The histories of the majority of the patients revealed the existence of a long standing gastric complaint. This, in the opinion of the author, suggests an etiologic relationship between the preexisting states such as gastritis, ulcer and polyposis, and the subsequent cancer. The former may therefore be properly regarded as precancerous states particularly in patients beyond 40 years of age. The symptom complex of the early stage of the gastric cancer is frequently vague. Dyspeptic complaints, progressive emaciation and blood in the feces in a middle aged person are to be regarded as suggestive of gastric cancer. The author stresses particularly the value of the x-ray study of the mucosal relief in the early diagnosis. The proper procedure in doubtful cases is an exploratory laparotomy combined, when necessary, with a gastrotomy. Conservative waiting in such cases will clear the diagnosis but will rob the patient of a chance of recovery. The early recognition and treatment of inflammatory processes of the stomach (gastritides) in the middle aged is to be regarded as prophylaxis against later development of a blastomatotic process.

**Central Control of Metabolism of Fats**—De Langen says that in a previous paper he pointed out that hyperlipemia not only accompanies anemia resulting from bleeding but also occurs when anemia is the result of injections of a hemolyzing substance. In both cases the fats and lipoids in the blood do not increase gradually in proportion as the hemoglobin content and the number of red blood cells decrease suddenly. If the anemia is not further increased, the fat curve rises as sharply as it previously dropped and becomes normal in the course of a few days. If the bleeding or the hydroxylamine injections are repeated, the same phenomenon is observed to occur at the same stage of the process. This rapid development of hyperlipemia gives the impression that it is under central control. A number of different methods have been applied in the effort to prove and localize this central control of the metabolism of fats. The author found that in rabbits which have been anemized about 50 per cent by one or other of the two processes mentioned and in which the spinal cord is cut between the third and fourth thoracic vertebrae, continued bleeding or injection of hydroxylamine does not elicit

hyperlipemia nor did it occur when the anemia was brought below 40 per cent. This absence of any increase in fats, which otherwise occurs regularly, suggests the possible existence of a central control. It was noted that lipemia can be induced in rabbits by the administration of sulfonmethane. After a highly lipemic serum had been observed in a patient with barbituric poisoning, the author studied the effect of barbituric acid preparations and of other hypnotics on the fat content of the blood. It was found that the various hypnotics differ in their effect on the fat metabolism. Barbituric acid preparations have a narcotic effect on the mesencephalon and various experiments with narcosis of the mesencephalon demonstrated that the hypophysis is involved in the fat metabolism. Discussing the problem as to how the increase in the fat content of the blood is brought about, the author calls attention to the role of the liver. There are a number of indications suggesting that the liver plays a major part in the metabolism of fats. The varying composition of the fats contained therein lend great probability to this hypothesis. In hyperlipemia, such as was produced by artificial anemia and by mesencephalic narcosis, fat accumulated in great quantities in that organ. The sudden rising and falling of the blood fat in anemic hyperlipemia suggests a regulating mechanism of a neurogenic nature. The great increase of fat in the blood produced by the action of barbituric acids and certain other hypnotics strengthens the conviction regarding this central regulation. Observations also support the view that there must be a center in the mesencephalon that plays some part in the regulation of the metabolism of fats. The results of investigation of the influence exerted by the anterior and by the posterior lobe of the hypophysis justify the supposition that the latter gland affects the center both positively and negatively. The fact that the influence of this center on the metabolism of fats is inhibited when the spinal cord is cut at the third thoracic vertebra indicates that the necessary stimuli connected are transmitted to the abdominal organs by the nerve pathways communicating with it. Finally, the changes noted as taking place in the liver during hyperlipemia point to the liver as the central organ which, in response to a central regulating mechanism, brings about the metabolism of fats.

**Porphyria and Classification of Porphyrins**—Eldahl differentiates forms of porphyrinuria without symptoms from those with symptoms. Discussing the group without symptoms, he mentions (1) the hereditary type, which may be either constant or periodic, (2) the symptomatic type, which is observed in fever, anemia and so on and (3) the medicinal type, which develops after medication with arsenphenamine and with certain hypnotics. With the group of porphyrinurias which present symptoms, the author classes (1) the disorder that is designated as porphyria, (2) the toxic form, which is caused by arsenic, lead or hypnotics, and (3) hydroa vacciniforme. He gives especial attention to the entity known as acute porphyria. This is an acute disease with the following symptoms: violent abdominal pains, obstinate constipation (rarely diarrhea), organic illness of the cerebrum and the medulla (insomnia, psychoses, multiple pareses), hepatic and renal insufficiency, elimination of chromogen and porphyrin in the urine. The cause is supposed to be a congenital and severe abnormality in the intermediary metabolism, a latent or relative insufficiency of the porphyrin synthesis, which through some cause may become absolute. The synthesis probably takes in the liver. Eliciting causes may be infections, overwork, psychic trauma and chemicals in small amounts. The prognosis is unfavorable. An acute attack is often fatal. The mortality varies but it averages around 70 per cent. The disorder is most frequent in women (about 70 per cent of all cases), those between the ages of 20 and 30 develop it most often and have the highest mortality. Porphyria may run in families. It has been traced through three generations. Regarding the treatment, the author says that in many cases dietetic treatment has been employed, an innocuous diet, such as the one formerly used in hepatic and renal diseases. Some authors use diuretics. This, however, does not seem justified when it is considered that edemas are never seen in porphyria. This treatment seems to have augmented the existing toxic injury to the organs. Sodium carbonate has been tried, because the urine in porphyria is strongly acid. The author doubts

that any effect has been obtained. Liver preparations have been used in many cases. The author employed the therapy which is now common in hepatic injuries and hepatitis, namely insulin and dextrose.

**Polycythemia Treated by Irradiation of Pylorus**—Andersen and his associates point out that in 1931 Hitzenger advanced the theory that pernicious anemia and polycythemia are diametrically opposite diseases, representing respectively the result of an underproduction and an overproduction of the intrinsic factor. In 1934 Hitzenger advocated resection of the pylorus organ as being the only causal therapy in polycythemia, but he acknowledged that resection is advisable only in cases simultaneously involving a juxta-pyloric ulcer. In two cases of polycythemia without ulcer, Hitzenger tried roentgen irradiation of the stomach. In one case the hemoglobin (Sahl) dropped from 140 to 100 per cent, the red cells from 8.9 to 5.6 million. In the other case the hemoglobin fell from 128 to 110 per cent, the erythrocytes from 9.5 to 7 millions. The result, however, was not permanent as the blood values rose again after a few months. Later Hitzenger seems to have abandoned irradiation of the stomach and recommended universal roentgen irradiation of the body as proposed by Sgalitzer. When the authors began their investigations on polycythemia they were unaware of Hitzenger's two cases. Based on Meulengracht's work on pernicious anemia they decided to try roentgen treatment of the isolated pylorus to obtain a diminution of the supposed overproduction of the intrinsic factor. This was regarded as more rational than the weakening of the bone marrow by irradiation of the entire osseous system. Discussing the technic of the roentgen irradiation, they say that the pyloric region can be reached through a cutaneous circular area approximately 9 cm in diameter. In order to locate the field, the patient is placed on the trochoscopes in a position identical to the posture occupied during the subsequent irradiation, i. e. resting on the back and with the same number of cushions under the head. Slight movements or even deep breathing may result in considerable displacement of the field. The patient is given a small portion of a fluid contrasting agent and a few minutes later the region is observed by fluoroscopic examination. In order to locate the field on the abdomen, the authors devised a localizer consisting of a metal ring with a diameter of 9 cm. The ring was placed on the abdomen under the fluoroscope so that it circumscribed the pylorus and the descending part of the duodenum. After the fluoroscope has been removed the circumscribed cutaneous area is marked off with a colored pencil. First the authors gave a series of four irradiations with two day intervals, at each irradiation 200 roentgens was applied through a filter of 0.5 mm of copper, with 150 kilovolts, 5 milliamperes and at a focus-skin distance of 40 cm. The next series consisted of three irradiations of 200 roentgens each, between the first and the second series there was an interval of one month. Thereafter the roentgen treatment was twice repeated with monthly pauses a series of three separate irradiations of 200 roentgens having been given at each treatment. The authors employed this treatment in a woman aged 77 who had polycythemia. In response to this roentgen irradiation of the pylorus the erythrocytes decreased from 11 to 4.1 million and the hemoglobin dropped from 138 to 100 per cent. The color index increased from 0.6 to 1.2 the mean diameter of the red cells from 7.29 to 7.81 microns.

## EXCESSIVE PHYSICAL EXERTION AND ITS EFFECT ON THE KIDNEYS

GEORGE SANFORD FOSTER, M D  
MANCHESTER, N H

The kidney is an organ of secretion and excretion that can carry a heavy load over a short period even while temporarily deranged from normal because of this extra load placed on it and yet has a most emphatic power of reconstruction and early return to normal when this load has been removed.

When one considers the masses as practically always overeating and underexercising, it appears that a certain degree of overload becomes somewhat normal. Not only do the masses overeat at each meal, in many cases they eat too often and nibble or lunch between meals too much.

Further to be considered are the forms of food eaten by the average person. The overindulgence in sweets and alcoholic drinks and the excessive ingestion of proteins merely emphasize the fact and make one the more appreciative of the high degree of resuscitation and regeneration given man when it comes to his kidneys.

Possibly no organs in the body suffer more disconcert and greater punishment throughout life than do the kidneys. On the other hand, possibly no organ, outside of the heart, is more essential to normal health. In the terms of the automobile salesman, the kidneys absorb grief in volumes and yet stand up and repeat this resuscitation and regeneration over and over again.

The particular interest of this special observation is the direct effect on the kidneys of extreme physical exertion over a period short of two hours as shown by the urinalyses made previous to and immediately after this extreme test of physical exertion.

This research was carried on with some twenty men each one being well trained, properly prepared and well schooled in distance running. By means of a thorough physical examination they were declared in good physical condition just previous to entering the contest.

In August 1937 these twenty trained and conditioned men competed in the well known Mount Washington run. During this run the contestants, starting at the base of Mount Washington, made the ascent by the famous carriage road to the summit, a distance of 8 miles. This 8 mile run has an average incline of 22 degrees during the entire distance, a rise of 4,800 feet. There are eighty curves in the road.

Thus it will be seen that this is a hard pull from start to finish. Not a foot of the distance is accomplished on level going. Because this is one of the

outstanding distance runs of this country the observations and research made in this instance are of extreme importance as far as any direct influence on the kidneys is concerned.

Possibly some data on the amount of foot-pounds of work used in making this run would be of interest. This is especially true because, with a background of such an amount of energy output, the influence on the kidneys becomes more valuable as a clinical entity. It further goes to show what remarkable regenerative organs the kidneys are.

An interesting phase of distance running is the foot-pound work done by the individual runner during each race. Set aside a penny a day and double it each day for one month, that will give an idea of what a distance runner accomplishes in compound interest of foot-pound work during any distance race. In 1875 when Professor Amen established the first record speed ascent on foot by the carriage road, the foot-pound work in accomplishing this feat was the same as it is today. This record stood for twenty-nine years.

In 1904 this record was lowered by fifteen minutes and stood at this mark for the next thirty-two years, resisting several attempts to break it. The foot-pound work was the same as used by Amen and by the one who lowered the record thirty-two years later. The difference was simply the variation in physical condition of the two men. In other words, the reserve left after each stride in foot-pounds was greater in the second runner than in the first. Each time the runner makes a stride in ascending the Mount Washington carriage road he uses 92 foot-pounds of work. Every distance runner must be in superb physical condition. The leg muscles must coordinate at all times during the entire run up the mountain. There must be even timing of the stride, and its constant length must not alter an inch. A well trained and properly conditioned muscle will not become fatigued even over a long period of exertion. The leg muscles have been massaged, lubricated and set into place so deftly that perfect coordination results during the entire run with a runner in good physical condition.

Every time a muscle is put under tension, energy material is lost. This energy material is termed glycogen or muscle sugar. Every fiber of each leg muscle must have a constant replacement of loss in this chemical substance if the individual fibers are to continue to function normally.

These runners ascending Mount Washington by the carriage road use in excess of 760,320 foot-pounds of work. This gives a foot-pound work tonnage of 380 tons. The heart, lungs, liver, and glands such as the pituitary and adrenal work as the second hand of a watch.

Red Blood Cells Four specimens showed many (from ten to twenty cells in each field) Three showed a few (from three to five cells in one out of every five fields) Two showed an occasional cell (from one to three cells in an occasional field) One showed one cell in every five to ten fields In eight none were seen

**Casts** Five showed many casts (from five to ten in each field hyaline and fine granular, short, narrow type) Two showed a few (from one to three in each field hyaline and fine granular, short, narrow type) Two showed a few granular casts only (short, narrow type from one to three in each field) Three showed a few hyaline casts only (short, narrow type from one to three in each field) One showed a rare hyaline cast only (short narrow type one in every three to five fields) In five none were seen

**Squamous Epithelium** Five showed a few (from three to five cells) in one or two out of every five fields examined Eight showed from one to three cells in an occasional field Two showed one cell in every five to ten fields In three none were seen

**Calcium Oxalate** Four showed many of these crystals (from twenty to thirty) in each field Five showed a few crystals (from three to ten) in each field One showed one, two or three crystals in an occasional field In eight none were seen Those seen were of the smaller variety

**Triple Phosphates** Eight showed a few (from two to five) crystals in an occasional field One showed an occasional crystal or two in an occasional field In nine none were seen

**Uric Acid** Seven showed many (from three to ten) crystals in each field Six showed a few (from one to five) crystals in an occasional field One showed a crystal or two in an occasional field, and in four none were seen

#### COMPARATIVE ANALYSIS WITH COMMENT

**Color**—Previous to the run three specimens were amber and after the run sixteen were a dark amber Previous to the run ten were yellow and after the run two were a deep yellow Previous to the run five were pale Hyperactivity of the skin combined with markedly augmented respirations no doubt resulted in a concentrated urine following the run with resulting deeper color

**Appearance**—Previous to the run all specimens were clear with the exception of five, which were but slightly cloudy when first voided After the run all were cloudy when first voided The forced circulation through the kidneys during the entire run produced some cellular or protein destruction resulting in the clouding

**Specific Gravity**—Previous to the run the highest was 1026 and the lowest was 1006 Following the run the highest was 1030 and the lowest was 1006 (The same individual specimen recorded 1006 on the two occasions) With the excessive activity of the skin and the respiratory and circulatory action, one would expect a rise in the specific gravity It would seem that the excellent physical condition of the runners would reflect a more favorable balance in the variation of specific gravity than in untrained persons This proves the fact

**Reaction**—Previous to the run all but one of the specimens gave an alkaline reaction (no doubt owing to the diet rather than to any nervous or emotional factor) Following the run all but three of these had become acid Here again the augmented circulation and the more complete cutaneous and pulmonary elimination no doubt played a very important part in the change from blue to red

**Albumin**—Previous to the run only four specimens showed any trace of albumin What their showing was for a week or more previous to this date is problematic As previously stated, no history of past urethral infections was ascertained

Following the run only three were free from some degree of albumin Here the destruction of protein in the kidney itself as well as in the blood stream would be a physiologic factor of the majority under such a severe physical strain

**Sugar**—Previous to the run 55 per cent of the specimens showed sugar present Following the run 77 per cent showed sugar present In the former instance, no doubt anxiety and apprehension play an important part None of the men gave a history of having shown sugar in the urine previously so far as they were aware of this fact The increase of 22 per cent following the run merely goes to show that excessive physical exertion has its emphatic but transitory influence on the pancreas and liver

**Examination of Sediments**—**White Blood Cells** Previous to the run twelve or 66 per cent of the specimens showed these present in the sediment in varying degrees Following the

run this percentage was increased to 93 per cent With the augmented circulation resulting in a higher kidney tension, this increase of 27 per cent is not beyond reason

**Red Blood Cells** Previous to the run two, or 11 per cent, showed their presence in a meager degree, how long this had been evident I cannot state

Following the run this was elevated to 50 per cent Here again the augmented circulation and resulting increase in intracapillary renal pressure must have been the causative factor

**Casts** Previous to the run seven, or 38 per cent, showed the presence of casts in a greater or lesser degree Following the run this was elevated to 66 per cent This increase of 28 per cent was no doubt due to the greater degree of temporary destruction of kidney tissue secondary to excessive physical exertion and its concomitant factors

**Calcium Oxalate Crystals** Previous to the run fifteen, or 83 per cent, showed the presence of calcium oxalate crystals Following the run the percentage was the same

#### SUMMARY

It is interesting to note the changes in the individual specimens voided just previous to as compared with the same individual specimens voided immediately at the completion of the run

1 *Color*—All specimens showed concentration, in other words a darker urine was voided at the finish than at the start This was true for each individual

2 *Appearance*—Previous to the run five were slightly cloudy At the finish the same individuals showed a definitely cloudy urine The same individual specimens showed an increase in specific gravity of from 2 to 10 points, with the exception of one specimen voided previous to the run but not in quantity sufficient to register the specific gravity None of these specimens gave evidence of the presence of albumin

All the other specimens voided at the finish were either cloudy or slightly cloudy These specimens were all clear at the start It is an interesting fact to note that of these thirteen specimens voided and clear at the start four showed no change in specific gravity at the finish while of the other nine specimens six showed an increase in specific gravity of from 2 to 12 points and three registered the same specific gravity as that of the specimen voided just previous to the start of the race

Further of these thirteen specimens showing clear at the start four gave evidence of albumin, one of these showed many casts in the urine (hyaline and fine, granular, short, narrow type), one showed an occasional white blood cell in the sediment, one showed a few white blood cells in the sediment The other specimen showed no cellular evidence or casts in the sediment

3 *Specific Gravity*—Ten of the specimens showed at the finish of the race from 2 to 12 points increase in specific gravity with an average individual increase of 6 points Four of the individual specimens showed the same specific gravity at the finish as at the start Three of the individual specimens showed a decrease one a loss of 6 points, one of 4 points and the other of 2 points In one instance the specific gravity at the start was not obtainable because of an insufficient amount of urine, thus no comparison could be made in the specimens of this individual

In each instance in which there was an increase in specific gravity, the albumin was absent previous to the run and present following the run This was also true in cases in which no change was found in specific gravity before and after the run The same can be stated regarding the two specimens showing a decrease in specific gravity at the finish as compared to the start

Previous to the race the albumin was not present, following the race tests for albumin were positive

4 *Reaction*—All but one specimen showed an alkaline reaction before the race. One specimen was acid. Probably this alkaline reaction, as previously stated, was due to the diet, since all the men ate at the same place for the two meals previous to the run. The man giving the acid reaction previous to the run arrived the morning of the race and therefore had eaten elsewhere. Since all specimens were refrigerated, this seems a very plausible deduction regarding the effect of the diet in this instance.

Following the race fourteen urines turned to acid. Three that had been alkaline in reaction previous to the race remained the same following the race. Peculiar

increase in specific gravity at the finish, one of 8 points and the other of 6 points. Six runners whose urines were negative to the solution at the start were positive at the finish. Of these six runners there was no change in specific gravity at the finish in the urine of two. Four showed an increase in specific gravity as follows: respectively 2 points, 4 points, 8 points and 12 points. Two runners gave negative results before and after the race. These showed increased specific gravity of 8 and 10 points respectively.

7 *White Blood Cells*—Twelve specimens showed white blood cells in varying degrees previous to the run (no check on previous urethritis). Eleven of these showed white blood cells in varying amounts following the race. One runner showing the presence of white

to himself, the one runner who showed an acid reaction previous to the race remained the same following the race.

5 *Albumin*—Eleven men whose urines were normal previous to the race showed the presence of albumin following the race. Four were positive both before and after the race. Three did not show the presence of albumin either before or after the race.

*Sugar*—Ten specimens were positive to Benedict's solution previous to the race. In eight of these cases the specimens were still positive at the finish of the race with a slight decrease in amount in one. Two of these specimens showed no change in specific gravity. Two showed an increase in specific gravity. Three showed a decrease in specific gravity. In one case there was an insufficient amount of the specimen to make a specific gravity test. The other two runners whose urines were positive to Benedict's solution before the start were negative at the finish. Both of these two showed an

blood cells in sediment previous to the run gave no evidence in urinary sediment after the run. (Evidently they were flooded away by the voiding previous to the run). Six runners who gave no evidence of white blood cells in the sediment previous to the run all showed them present in varying degrees following the run. Here intracapillary renal tension could be the causative factor.

8 *Red Blood Cells*—Two specimens showed red blood cells present in the sediment previous to the run. In one of these red blood cells persisted after the run and one showed none in the sediment after the run. Sixteen did not show red blood cells in the sediment previous to the run. Following the race nine of these showed the presence of red blood cells in the sediment in varying amounts while seven showed no red blood cells in the sediment.

9 *Casts*—Eleven did not show evidence of casts in the sediment previous to the run. Following the race

nine of these same runners showed casts in varying numbers (hyaline and fine granular, short, narrow variety) while two did not show casts in the sediment. Seven showed the presence of casts in the sediment previous to the run in varying numbers (hyaline and fine granular, short narrow type). Following the race four of these still showed casts of the same relative types and numbers, while in the other three instances no casts were found in the sediment.

Some kidneys show a fuller degree of compensation and a higher degree of resistance than others. This would seem to be a personal factor as to fitness.

**10 Calcium Oxalate Crystals**—Fifteen showed calcium oxalate crystals present in varying amounts in the sediment previous to the run. Three gave no evidence of these present in the sediment previous to the run. This undoubtedly shows the influence of anxiety and apprehension in producing these crystals. Following the run, of the fifteen showing the presence of these crystals previous to the run nine still persisted in varying amounts, while six gave no evidence of these crystals in the sediment. Previous to the race three gave no evidence of calcium oxalate crystals in the sediment while after the race one of these showed these crystals in the sediment and the other two still gave no evidence of the presence of these crystals.

## RELATION OF PHYSICAL EXERTION AND EMOTION TO PRECIPITATION OF CORONARY THROMBI

J C PATERSON M.D.

REGINA, SASK., CANADA

Until quite recently it was generally agreed that excessive physical exertion or emotion was intimately connected with the precipitation of coronary thrombi. Fitzhugh and Hamilton<sup>1</sup> and Sproull,<sup>2</sup> from analyses of the histories of their cases, concluded that coronary occlusion was preceded as a rule by departures from ordinary habits of living. During the last two years, however, some doubt has been expressed regarding this relationship. Phipps<sup>3</sup> and later Master and his co-workers<sup>4</sup> in statistical surveys have shown that approximately 40 per cent of attacks of coronary thrombosis are initiated while the patient is either asleep or at rest and that in only a small number is the attack immediately related to unusual exertion or emotion. The latter authors conclude that their results seem to eliminate exertion or excitement as factors in the precipitation of coronary thrombi. Such a conclusion implies that coronary thrombi are initiated and progress to the point of occlusion in a short space of time—an inference that has no pathologic basis. Actually there is definite evidence to prove that hours or even days elapse between the time of the inception of the thrombus and the moment when occlusion, with its resulting cardiac pain, occurs. To demonstrate this, one has only to study the structure of the occluding thrombus in a person who, previously in apparently

good health, collapses and dies with the onset of cardiac pain and before infarction has had time to take place. If a serial section is made through the entire length of the thrombus, some levels will show the process to be many hours or days old. The following two cases illustrate the gradual nature of the formation of a thrombus.

**CASE 1**—A man aged 54 collapsed suddenly on the street and died before he could be hospitalized. No previous history was obtained. Autopsy revealed marked coronary sclerosis and recent thrombosis of the left anterior descending coronary branch. The left circumflex artery, at its immediate origin, showed a localized area of intimal hemorrhage without thrombosis of the adjacent lumen. The thrombus in the left anterior descending branch measured 1.5 cm in length. The affected part of this artery was embedded in one block and sectioned serially at intervals of 7 microns from one end to the other, the sections being cut horizontally. Every section was stained and examined.

At certain levels the thrombus consisted, morphologically, of two distinct portions. First there was a small, oval, radiating mass of condensed material which was localized to one side of the lumen and which showed invasion by fibroblasts in some sections. Second there were masses of more loosely arranged networks of fibrin and platelets in which red cells and leukocytes were enmeshed (fig 1). In many of the sections only the latter type of thrombus material could be found and in some it occupied the entire lumen.

The older portion of the thrombus was attached to the endothelium immediately adjacent to a point of marked hemorrhage into the inner aspect of an atheromatous focus. The serial sections failed to reveal a break in the tissues lying between the hemorrhage and the thrombus nor was there any atheromatous material incorporated in the thrombus. At the point of attachment of the older thrombus mass a rounded structure resembling a thrombosed capillary was seen in the subendothelial tissue. Otherwise there was little evidence of intimal vascularization. The occluding thrombus lay on one side of a point of stenosis of the lumen but the relation of the stenosing plaque to the direction of blood flow was not ascertained.

**CASE 2**—A man aged 68 was found dead in a hotel bedroom. He was fully dressed and was kneeling at the side of his bed. From the degree of rigor mortis that had set in it was estimated that death had occurred about three and one-half hours after he had left work, at which time he had not complained of any pain but appeared to be in his usual state of good health. Autopsy revealed a recent thrombus occluding the left circumflex coronary artery at a point about 0.7 cm from its origin. Immediately proximal to the thrombus the lumen was markedly stenosed by an atheromatous plaque. At the distal extremity of the thrombus the intima was slightly raised by a small, reddish black mass which appeared to be a hemorrhage into an atheromatous focus. A similar but larger intimal hemorrhage was noted in the left anterior descending branch about 1 cm from its origin. The endothelium overlying both intimal hemorrhages appeared to be intact. The hemorrhage in the left anterior descending branch showed no gross evidence of thrombus formation in association with it nor was there any stenosis of the lumen in its vicinity. The thrombosed portion of the left circumflex artery was embedded in one block and was sectioned serially at intervals of 10 microns throughout its entire extent. The sections were cut longitudinally in an attempt to demonstrate the relation of the occluding thrombus to the point of stenosis previously mentioned. Sections were mounted and stained at intervals of about 200 microns.

Microscopically the thrombus consisted first of an older organizing portion which was adherent to the intima immediately distal to the apex of the stenosing atheromatous plaque (fig 2). From the amount of fibroblastic proliferation in this part of the thrombus there is reason to believe that it was at least three days old. Secondly there was a mass of fibrin and platelets with enmeshed red cells which was attached to the older thrombus and which apparently completed the occluding process.

Two points of microscopic hemorrhage were noted in the intima underlying the thrombus. Immediately below the attachment of the older portion of the thrombus there was a mass of pink-staining organizing material which resembled clotted blood and in which a large amount of hemosiderin was demonstrated by Perl's stain (fig 3). A few small capillaries were seen in this area of old hemorrhage. Distal to the entire thrombus

Fig 1—An oval mass of radiating and organizing thrombus material attached to the endothelium at a point at which hemorrhage had occurred into an atheromatous focus (case 1). To the left of this older thrombus a small fragment of more recently formed thrombus material lies free in the lumen. In other sections this propagated thrombus occluded the lumen completely. Hematoxylin and eosin stain slightly reduced from a photomicrograph with a magnification of 80 diameters.

mass, and apparently in no relation to it, the endothelium was elevated by an intimal hemorrhage in which the red cells were intact. Random sections made through the discrete hemorrhage noted in the left anterior descending branch showed the adjacent lumen to be free from thrombus formation. This hemorrhage had occurred into a large atheromatous focus, and in the sections studied it was separated from the lumen by a thin layer of dense tissue. In the latter layer, numerous capillaries were seen to enter the hemorrhagic focus and to run in the direction of the lumen, although their actual connection with the lumen was not demonstrated.

Because of the evidence of organization, the invasion by fibroblasts, in the older portion of the thrombus in each of these two cases the inception of a thrombus must have occurred at least three days before death. There is no reason to believe that any unusual symptoms were experienced either at the time of the initial thrombus inception or in the ensuing latent period. Both persons were pursuing their ordinary activities until just before their fatal attacks, and patient 2 was known to have been without complaints and in good spirits three and one-half hours before his death. In this case microscopic examination of that part of the myocardium supplied by the occluded artery failed to reveal any evidence of infarction. It may be concluded, therefore, that death had followed coronary occlusion so rapidly that sufficient time had not elapsed for infarction to occur. In other words, this case does not belong to the "silent" group in which coronary thrombosis with infarction occurs without definite signs and symptoms resulting. The immediate cause of death in each of the two cases appeared to be the terminal occlusion of the coronary lumen by a recently formed mass of thrombus material superimposed on and propagated from an older thrombus which was at least three days old. The formation of a thrombus in these two persons, then, was a gradual and not a

rapid process. Therefore, to eliminate physical exertion or emotion as a precipitating factor in coronary thrombosis, the activities of the patient should be investigated not only for the few hours prior to the attack but for many days previously.

On purely pathologic grounds there is reason to believe that such physical and mental states, both of which result in temporary hypertension, cannot be excluded as precipitating factors of coronary thrombosis. In both of the cases reported here, as well as in thirty-one of thirty-six consecutive cases reported elsewhere,<sup>5</sup> hemorrhagic foci were seen in the intima at the site of thrombotic occlusion (fig 3). The mechanism of production of intimal hemorrhage has already been described in detail,<sup>6</sup> my original observations and in part my conclusions having been confirmed by Wartman<sup>7</sup> and by Winternitz and his co-workers.<sup>8</sup> Stated briefly, this lesion results not from the backflow of blood through an intimal defect produced by the rupture of an atheromatous "abscess" as was previously thought, but from the rupture of discrete capillaries which are derived from the coronary lumen. Intimal capillaries are a common finding in the tissues adjoining most intimal hemorrhages, and if a careful section is done they may sometimes be shown to arise from the lumen of the artery and to enter the hemorrhagic focus. Capillary rupture with ensuing hemorrhage into the intima is not confined always to the points of thrombotic occlusion.

Fig 2—Longitudinal section through the occluded portion of a coronary artery in case 2. An older organizing mass of thrombus is attached to the apex of a stenosing arteriosclerotic plaque. Arising from this older thrombus is a large mass of more recently formed thrombus material which completed the occluding process. Hematoxylin and eosin stain slightly reduced from a photomicrograph with a magnification of 130 diameters.

sion. The hemorrhagic lesions are frequently multiple, as in the two cases cited in this report, and they may and do occur without associated thrombosis of the adjacent coronary lumen. However, it has been suggested that if the hemorrhage with its concomitant

tissue damage occurs at a point at which a stenosing arteriosclerotic plaque has produced stagnation and eddying of blood, conditions may then be favorable for the deposition of a thrombus.<sup>5</sup>

In the final analysis, then, the factors responsible for the rupture of intimal capillaries should be the immediate causes of the precipitation of coronary thrombi. Two principal factors appear to be involved in the mechanism of capillary rupture: (1) softening, by atheroma, of the tissues surrounding and supporting the capillary wall, and (2) high intracapillary blood pressure. The influence of atheromatous degeneration on the production of capillary rupture has been

Fig. 3—A similar section to that shown in figure 2 showing an area of old intimal hemorrhage in the tissues underlying the attachment of the older thrombus. Perl's stain and hematoxylin and eosin stain slightly reduced from a photomicrograph with a magnification of 70 diameters.

described in detail elsewhere.<sup>9</sup> Intimal hemorrhages have been found to occur almost exclusively in areas of atheromatous degeneration. It is assumed that softening, which is a physical character of atheroma, allows the pressure of blood within the capillary to dilate its walls to such an extent that rupture eventually occurs. This assumption is borne out by the fact that intimal capillaries are usually of small caliber as they traverse the denser intimal layers, while they are frequently dilated in areas of atheroma. Furthermore, the age incidence of coronary thrombosis and intimal hemorrhage corresponds roughly with that in which atheroma usually develops, i. e. late middle age. Younger persons with characteristically dense and fibrous arteriosclerotic lesions, and elderly persons with heavily calcified plaques, are not so prone either to intimal hemorrhage or to coronary thrombosis.

The factor of high intracapillary blood pressure as a cause of capillary rupture is equally important, and it is with this factor that excessive exercise or emotion is concerned. Intimal capillaries, because they arise directly from the main coronary lumen, are exposed constantly to a relatively high pressure of blood. They are not, like other capillaries, at the end of a long series of arteries and arterioles which absorb much of the pressure by friction. Therefore it seems logical to assume that intimal capillaries, because of their

peculiar position, will be sensitive to sudden increases in the coronary blood pressure. If such an increase in the coronary blood pressure occurs, these capillaries will be in imminent danger of dilatation and rupture, particularly if the surrounding tissues are in a state of lability from atheromatous degeneration. Sudden and temporary increases in the coronary blood pressure are encountered commonly in circumstances of unusual exertion and emotion. With strenuous muscular exercise the systolic blood pressure is said to rise to from 160 to 180 mm of mercury. A corresponding rise in the diastolic pressure, although to a lesser degree, also occurs. Emotional stress, often but not always, results in a similar sudden increase in the systolic and diastolic pressures. For example, I have heard of a marked increase in the blood pressure of a young woman each time she recounted the details of a particularly harrowing experience.<sup>10</sup> This woman showed a normal variation in blood pressure of from 120 to 140 mm systolic and from 80 to 95 mm diastolic. During an emotional upset the systolic pressure varied from 150 to 180 mm and the diastolic from 100 to 120 mm.

It is suggested, therefore, that high coronary blood pressure, the result of strenuous exercise or of emotion (or of persistent hypertension), is one of the underlying causes of capillary rupture and intimal hemorrhage in arteriosclerotic coronary arteries. If conditions are favorable, the various changes which result from capillary rupture may then be the initiating factors in the deposition of coronary thrombi.

#### SUMMARY AND CONCLUSIONS

The formation of coronary thrombi is a gradual process, sometimes occupying several days before occlusion of the coronary lumen with its resulting cardiac pain is produced. Therefore the activities of a patient immediately preceding the onset of an attack of coronary thrombosis have no relation to the etiology of the precipitation of a thrombus but are purely coincidental. The pathologic appearances in a series of fatal cases of coronary thrombosis suggest strongly that excessive exercise and emotional stress are intimately concerned in the mechanism of coronary artery thrombosis.

<sup>10</sup> Prof. Duncan Graham, University of Toronto. Personal communication to the author.

**Medical Logic**—My main conclusion lies in advocating a new recourse to scientific logic in the sense of Francis Bacon to a 'taking thought for the morrow,' in spite of the Biblical injunction to the contrary. The last wave of pure reasoning beginning three centuries ago, would seem, indeed, to have started something. Experimentation and inductive logic, doubt and the penetration into the field of causation, have carried us thus far in the process of unraveling nature. Do we now need a new kind of reasoning? I leave this to the examination of the logicians in whom I have more confidence for their stimulus to scientific discovery than some of my fellow experimenters would grant them. What we now need, I believe is a new line of approach to a very old problem, namely, to the nature of life. I foresee not, in all probability, the centuries that have been required to establish the methods of experimentation that have given us real insight into the nature of causes but years at least before the essential nature of life is revealed. Claude Bernard gave us real hope through his insistence that biological problems are not only approachable experimentally, but that the laws of life are essentially those that govern inorganic bodies. Vital phenomena differ from inorganic phenomena in their spontaneity, their unpredictability.—Gay, Frederick P. *Medical Logic*, *Bull. History of Medicine* 7: 6 (Jan.) 1939.

# THE EFFECT OF TOBACCO SMOKING ON THE ALIMENTARY TRACT

AN EXPERIMENTAL STUDY OF MAN  
AND ANIMALS

J. G. SCHNEDORF, PH.D., M.D.

AND

A. C. IVY, PH.D., M.D.

CHICAGO

Present day concepts concerning the effects of tobacco smoking on gastrointestinal activities are based chiefly on clinical or personal experience. Many physicians can cite the history of one or more patients who were relieved of peptic ulcer, the ulcer syndrome or "unstable colon" when tobacco smoking was prohibited. However, little experimental data exist on which to base an explanation of the clinical observations referred to, and one is forced to reason a priori from the effects of various and frequently toxic doses of nicotine on animals and their isolated tissues or from the acute toxic manifestations experienced as a result of the "first smoke."

We have studied systematically the effect of smoking from one to several cigarettes on the various activities of the alimentary tract of normal human subjects, of patients with ulcer and of dogs. None of our subjects were required to smoke until the stage of acute toxic manifestations resulted, with the exception of three patients with duodenal ulcer, who reported that they became sick when they smoked "on an empty stomach."

## SALIVARY SECRETION

We first studied the effect of smoking on salivary secretion. Fifteen chronic cigaret smokers and five nonsmokers served as subjects. We used the method of Holck and Carlson<sup>1</sup> except that we did not use an ejector for the removal of the saliva.

The flow of saliva was stimulated in every subject except two of the chronic smokers. The group averages are shown in table 1.

Smoking stimulates the flow of saliva reflexly, the buccal mucosa is irritated by the smoke. The flow of saliva is not stimulated by the nicotine absorbed from two or three cigarettes. This was shown by injecting 0.4 mg. of nicotine subcutaneously into five smokers and five nonsmokers. This is the amount of nicotine that is usually absorbed from two cigarettes of the type used in our experiments. This amount of nicotine did not stimulate the flow of saliva (table 2).

No salivary stimulation occurred in two of the chronic smokers. The failure of tobacco smoke to cause salivary secretion in occasional subjects must be due to a "conditioned or learned inhibition" of salivary secretion to smoking, to an insensitive buccal mucosa or to a nicotine block of sensitive salivary ganglions.<sup>2</sup>

## GASTRIC MOTILITY

**Hunger Motility.**—We found that the hunger contractions of the stomach in man cease after the first few puffs of smoke. The hunger contractions when inhibited by smoking one cigaret may not recur for

from fifteen to sixty minutes after cessation of smoking. These observations confirm those of Carlson<sup>3</sup> and Danielopolu.<sup>4</sup>

The promptness with which the contractions are inhibited was interpreted by Carlson<sup>3</sup> as indicating a reflex inhibition and not a nicotine inhibition. By a series of analytic experiments on the dog we have found the motor pathway by which the contractions are inhibited. The observed facts will be listed. The subcutaneous injection of 1 mg. of nicotine into well trained, unanesthetized dogs did not inhibit the hunger contractions, but the inhalation of cigaret smoke by well trained dogs inhibited hunger contractions promptly. When three dogs who had undergone celiac ganglectomy and splanchnicotomy inhaled the smoke, inhibition occurred. In three dogs with the vagi sectioned above the diaphragm the inhalation of the smoke had no effect on hunger contractions.

Thus tobacco smoke inhibits hunger contractions through a reflex mechanism, the motor side of the reflex arc is in the vagi. The evidence also shows that ordinary amounts of nicotine do not produce gastric motor effects by acting directly on the local gastric ganglions, by raising the blood sugar content or by causing a discharge of epinephrine. Although tobacco smoking inhibits hunger motility through a reflex mechanism, it does not follow necessarily that all the effects of smoking on the alimentary tract are similarly produced.

TABLE 1—Effect of Cigaret Smoking on Salivary Secretion  
(Two or Three Cigarets Were Smoked)

	Basal Control (Average Cc per 15 Min.)	Smoking (Average Cc per 15 Min.)	After Smoking (Average Cc per 15 Min.)
Ordinary cigarettes Smokers* (15)	60 variation 1 to 10	106 variation 20 to 200	60 variation 3 to 10
Nonsmokers (5)	6 variation 2 to 10	126 variation 70 to 200	64 variation 20 to 110
Denicotinized † cigaret	Control 10 Min.	Smoking 10 Min.	Post-smoking 10 Min.
Smokers	49	87	49
Nonsmokers	49	94	49
Ordinary cigarettes Smokers	47	86	40
Nonsmokers	49	117	49

\* One subject showed no change on smoking; another a 14 per cent decrease in salivary output.  
† The smoke of the denicotinized cigarettes contained less than 1 per cent nicotine.

**Emptying Time of a Test Meal.**—Our experiment on the effect of smoking cigarettes on the emptying time of a test meal were performed as follows. The subject reported in the morning without breakfast. All the subjects were accustomed to taking the stomach tube. The stomach was emptied of its fasting contents, and 250 cc. of beef tea with three crackers was ingested. After one hour the stomach was emptied. Two or three tests were performed on each subject without smoking and two or three tests with smoking. In the smoking tests the subjects smoked two cigarettes during one and one-half hours before the test meal and three or four cigarettes while the meal was in the stomach; i.e., one cigaret each fifteen or twenty minutes. The tests were performed on seven normal chronic smokers and on twenty-two patients with duodenal ulcer, and all experi-

whether they smoked or did not smoke. Two, however, showed a slight but significant delay (subjects 3 and 4). The acidity of the gastric contents was definitely diminished in four of the seven subjects. This decreased the average acidity of the group (table 3).

In the patients with ulcer (table 3) smoking had no significant effect on the rate of gastric emptying of the group as a whole, neither did smoking influence the acidity of the gastric contents of the group. In only one subject (subject 13, a smoker) was a significant delay observed. The average retention in this patient was 50 per cent.

Thus the smoking of from three to four cigarettes during one hour by normal smokers or by patients with duodenal ulcer usually did not delay the emptying of a test meal from the stomach. When any effect was observed, it was in the direction of an inhibition of gastric evacuation and gastric secretion. Dickson and Wilson<sup>5</sup> observed a slight decrease in gastric motility in four subjects when several pipes or cigarettes were smoked just before or during the evacuation of a barium sulfate meal. Of course this tendency toward reduced gastric motility and toward retention may be exaggerated when solid food is ingested, but we have not performed experiments to determine the truth of such an assumption.

#### GASTRIC SECRETION

Gray<sup>6</sup> is the only author who has made a serious attempt to study the effect of smoking on gastric secretion. He studied fifty patients with functional gastric symptoms attributable to smoking and reported that smoking on an empty stomach or after a test meal increased the volume of fasting contents and caused hyperacidity in some patients complaining of heartburn, hypoacidity associated with gastritis in others and a variable response in patients with duodenal ulcer. He

did not present values for acidity and did not state the number of determinations made on each patient. Neither did he state that he had his patients avoid the swallowing of saliva, which might alter the gastric values observed.

Skaller<sup>7</sup> studied the effect of nicotine on the secretion of animals with a gastric pouch but he did not record values for acid and he used relatively enormous doses of nicotine (20 mg), hence his work is of little value.

**Continuous Fasting Secretion**—We have studied the effect of smoking from four to seven cigarettes over a period of one hour and fifty minutes on the fasting secretion of twenty-five smokers, fifteen nonsmokers and twenty patients with duodenal ulcer. The fasting contents were removed with a Rehfuess tube, and the subjects were told to expectorate all saliva. The basal secretion for four ten-minute periods was determined by continuous aspiration, and then smoking was started, the volume of secretion obtained every ten minutes was recorded and the acidity titrated. This was repeated at least twice and usually three times on each subject.

In only one of the forty normal subjects (subject 12), were the volume and acidity of the fasting secretion augmented. In seventeen of the forty no statistically significant change occurred, while in twenty-two an appreciable decrease in volume and acidity resulted.

In only one of the twenty patients with ulcer (a nonsmoker) did any significant increase in gastric acidity of the basal secretion result, eight showed no significant change, eleven showed a decrease in acidity. The results are summarized in table 4. The differences between the results obtained with demicotinized and with ordinary cigarettes were not statistically significant. There was a tendency, however, for the demicotinized cigarettes to depress gastric secretion less.

These tests were repeated on six chronic smokers and six nonsmokers who were told to swallow their saliva. On smoking, either no change or a slight decrease in acidity resulted.

The effects of smoking two cigarettes on the fasting secretion of four dogs with a Pavlov pouch was studied.

\* Saliva was not swallowed. A bouillon test meal with three crackers was used. Three or four cigarettes were smoked in one hour.

† Two showed a slight but significant retention; the acidity was significantly diminished in four.

‡ In one a significant retention occurred with smoking. In no instance was the rate of evacuation significantly lessened.

These dogs smoked through a small trocar inserted into the trachea during local anesthesia at intervals for an hour. A slight depression of the volume and acidity of the secretion resulted. We also perfused 50 cc of water, through which the smoke of two cigarettes had been drawn, through the stomach of a dog with a pouch made of the entire stomach. No stimulation of acid secretion

occurred, although an increase in mucous secretion resulted. We also introduced into the intestine of dogs with a pouch of the entire stomach a similar quantity of water through which the smoke of two cigarettes had been drawn, gastric secretion was not stimulated. When the smoke of four cigarettes was used, some of the dogs vomited, as might be expected, and the secretion of acid was depressed.

TABLE 4—Effect of Cigaret Smoking on Fasting Gastric Secretion in the Normal Subject and the Patient with Ulcer

Subject	Control, 30 Min *					Smoking 4 to 7 Cigaretts				
	10 Minute Volume Cc	Acidity (Chlorine Units)		Total HCl Output Mg		10 Minute Volume Cc	Acidity (Chlorine Units)		Total HCl Output Mg

Normal smokers (25)†	13.4	46.9	57.3	22.0	28.0†	9.8	32.2	42.5	11.5	10.2
						10.1	41.1	51.8	10.2	10.9
Normal nonsmokers (10)	12.0	30.7	42.2	14.8	10.3†	9.7	28.0	36.5	9.7	12.6
Patients with ulcer (20)‡	23.2	45.2	55.3	38.9	47.0	19.8	37.2	48.0	20.9	33.0
						20.6	37.9	49.3	29.8	37.4

\* Saliva was not swallowed, the stomach was emptied by continuous aspiration, the basal ten minute flow was determined for forty minutes then from four to seven cigarettes, four for nonsmokers, were smoked during 1.5 hours; the flow of juice being recorded every ten minutes.  
† Denicotinized cigarettes containing less than 1 per cent nicotine were used.  
‡ The difference between the acid output of normal smokers and of nonsmokers is of doubtful statistical significance. A larger series of subjects would be required to demonstrate a difference if it exists.

When nicotine was given subcutaneously to fasting dogs with gastric pouches in a dose of 0.2, 0.4 or 1 mg., or in doses representing the nicotine absorbed from the smoke of one, two and five cigarettes of the kind we used in our work, a stimulation of acid production did not occur. Either no change or a decrease in acid production of the fasting stomach resulted. Depression always occurred if there was nausea and vomiting. Numerous experiments were performed.

Summarizing, the smoking of an ordinary number of cigarettes increased the acid output of the fasting stomach in only two of sixty human subjects, and the increase was so slight as to be of doubtful practical significance. Depression of gastric acidity occurred much more frequently. In dogs nicotine (0.2, 0.4 and 1 mg.) or tobacco smoke in any form either had no effect or caused a decrease in the secretion of acid by the fasting stomach.

**Digestive Secretion**—The results shown in table 3 demonstrate that the smoking of three or four cigarettes after a test meal does not cause a significant increase in the acidity of the gastric contents.

This observation on the human subjects was checked by experiments on three dogs with a Pavlov pouch. The response of the three dogs to a standard meal was determined in four experiments with and without the subcutaneous injection of 1 mg. of nicotine. The results in table 5 show that the nicotine had no effect on the secretory response of two of the dogs but depressed the acid output of the third, a smaller dog.

**Conditioned Gastric Secretion Reflex to Smoking**—The possibility of a conditioned gastric secretion reflex to smoking was considered because two subjects showed a slight increase in gastric acidity after smoking, whereas our dogs showed either no change or a depression of acid output. This possibility was studied with

twenty normal subjects, ten smokers and ten nonsmokers. The twenty subjects were specially selected because none of them on repeated tests showed an increase in acid output on smoking. The ten chronic smokers were asked to stop smoking for one week. Then the twenty subjects were asked to smoke a cigarette just before eating their meals and one or more immediately after eating. In this way we hoped that smoking would serve as a conditioned stimulator of gastric secretion, just as smelling or tasting food does.

In six of the twenty subjects an increase in the acidity of the gastric juice occurred in response to smoking, but the increase was not marked. The volume was increased in only two of the six subjects during one of the postconditioning test weeks. A human subject when conditioned to a dessert, such as an orange, responds by showing an increase in both volume and acidity. Thus we doubt whether any of the subjects were actually conditioned to secrete in response to smoking. We cite the observed facts, however, because in sleep the acidity of gastric juice may increase without an increase in volume.

**The Effect of Learning to Smoke on the Fasting Secretion of the Stomach**—The process of learning to smoke by the nonsmokers in the preceding experiment rendered it possible to determine the effect of smoking a minimum of six cigarettes a day on the fasting secretion of the stomach of a controlled group of ten human subjects. This was of interest because the average acidity of the fasting secretion of twenty-five smokers was higher than that of fifteen nonsmokers, although the difference was of doubtful significance from the statistical point of view (table 4).

The results are shown in table 6. A significant increase in acidity occurred in only one subject of the ten. When the averages of the ten subjects were determined, a significant difference before and after smoking was not found, the trend is toward a slight decrease. The group studied was too small to warrant any definite conclusion, however.

TABLE 5—Effect of a Subcutaneous Injection of 1 Mg. of Nicotine on the Gastric Secretory Response to a Standard Meal of a Dog with a Pavlov Pouch the Secretion Being Collected for Six Hours

\* Amount of nicotine usually absorbed on smoking five of the kind of cigarettes employed in our work.

**Secretion of Bile**—Inhalation of the smoke from one or two cigarettes or the subcutaneous or intravenous injection of from 0.2 to 1 mg. of nicotine was found to have no effect on the bile output of six anesthetized dogs with a biliary fistula, except as related to marked changes in blood pressure. These doses had no effect on the intragallbladder pressure of four dogs.

**Pancreatic Secretion**—In anesthetized dogs with the pancreatic duct cannulated the inhalation of smoke from two cigarettes or the injection of from 0.2 to 1 mg. of nicotine had no effect on the continuous secretion. When a continuous flow of pancreatic juice was main-

tained by the constant injection of secretin at a timed rate, the aforementioned doses of nicotine and smoke had no effect. The same was true when 2 mg of nicotine was given intravenously over a fifteen minute period, but when 2 mg of nicotine was injected at once intravenously, so as to cause a temporary fall in blood pressure followed by a marked and prolonged rise, then, as reported by Edmunds,<sup>8</sup> the flow of pancreatic juice

\* This increase in acidity was significant.

† The differences after taking up smoking are not significant. The group was too small to warrant any conclusion.

was decreased. This type of response would occur in man only when marked alterations in blood pressure result from smoking.

In the experiments on the effect of smoking on the biliary and pancreatic secretion of the dog, the blood pressure was recorded. The tracheal inhalation of the smoke of one or two cigarettes caused a rise in blood pressure of from 10 to 40 mm of mercury in twelve of eighteen dogs and a fall of 20 mm in the remaining three.

**Cardiovascular Effects**—Three (ulcer patients) of sixty chronic smokers with an empty stomach and a gastric tube in place threw up the tubes and fainted after smoking two or more cigarettes. These subjects told us beforehand that during fasting their tolerance for tobacco was very low. These patients were advised to quit smoking.

**Effect of Cigaret Smoking on the Number and Consistency of the Stools and on Gastrointestinal Passage Time**—It is generally believed that smoking increases the motility of the colon and promotes the urge to defecate. In a questionnaire study conducted by Walsh, Ivy, Laing and Sippy<sup>9</sup> among more than 1,000 students of college age, less than 1 per cent reported that smoking tended to "constipate." Of the men 13.7 per cent and of the women 17.3 per cent reported that excessive smoking tended to cause extra stools. However, the idea that smoking increases the frequency of urges or augments the activity of the colon may belong to the same category as the idea that smoking is conducive to peptic ulcer and aggravates its symptoms. That is, the anxiety factor, for example, may be at the same time the cause of excessive smoking and the aggravation of the peptic ulcer or of the unstable colon. It is well known among medical students that during examination week the consumption of cigarettes and the passage of extra stools are increased.

9. Walsh E. L., Laing G., Sippy B. W. and Ivy A. C. Unpublished data.

Pharmacologically, Hatcher<sup>10</sup> has shown that application of nicotine to the floor of the fourth ventricle increases the excitability not only of the vomiting center but also of the defecatory center and excites the motility of the colon. The intravenous injection of nicotine in the dog increases the motor activity of the colon.

For our study we used twenty medical students, ten smokers and ten nonsmokers, who were selected because they manifested stable habits as to stools. Two of the nonsmokers were selected because one normally defecated only every other day and the other every third day and because we thought that they should show an effect, if the others did not. We similarly selected three students who normally defecated twice daily. The tests were performed at a period when the students were not burdened with examinations and when they could follow a definite daily routine.

The dietary habits were ascertained and a dietary menu was prescribed so as to keep the quantity and quality of the food intake constant, i. e. the only variable factor was smoking or nonsmoking. During the experimental periods knotted colored strings were used as markers, the strings being given with the noon meal. The nonsmoking and smoking periods were seven days in length, and each stool was examined. The time of the first and last appearance of the daily markers was noted, as well as the time of passage of 75 per cent of the markers for any particular day. The smokers

ceased for a week and then resumed smoking, the nonsmokers were observed for one week and then they started to learn to smoke and continued to smoke for at least four weeks. A minimum of six cigarettes a day were smoked, and the nonsmokers were instructed to smoke slowly at the start, so as to avoid subjective toxic symptoms.

10. Hatcher R. A. and Weiss S. Studies on Vomiting. *J. Pharmacol. & Exper. Therap.* 22:139 (Oct.) 1923.

The data cannot all be presented, but the essential portion of the results is recorded in tables 7, 8 and 9. Although the number of subjects and the time they were studied is limited, several points of interest are to be noted. (We feel that we should apologize for the limited number of subjects, but it is expensive to maintain even twenty subjects on a diet for several weeks.)

The results may be briefly summarized as follows:  
1 In five of the twenty subjects smoking had no effect.  
2 In twelve of the twenty subjects smoking tended to increase the propulsive activity of the colon, but the gastrointestinal time was speeded up in only two of the twelve. Smoking made a daily stool possible in three of the twelve and it made the movements more complete in three more. It caused alternate diarrhea and constipation in two of the ten subjects who were learning to smoke.  
3 Smoking caused a decrease in the number of stools or increased their firmness in three of the twenty subjects.  
4 There was no correlation between these effects and the number of cigarettes smoked daily. As is well known, there is a considerable individual variation in tolerance to tobacco.

The results obtained by a systematic study confirm the general impression now currently accepted that smoking tends to augment the motor activity of the colon.

APPETITE

Smoking, at least excessively, is reported by numerous smokers to decrease appetite. We obtained no data on this question. It certainly depresses hunger motility, which in turn may diminish appetite.

COMMENT

In order to understand the variable effects of smoking on the alimentary tract, several well known facts must be borne in mind. First, acutely toxic doses of tobacco or nicotine provoke vomiting and defecation or diarrhea, these acts are under reflex control. In the

presence of mild nausea gastric tone and motility are depressed, but just before or during the act of vomiting the stomach, particularly the pyloric antrum, is very active. Second, the degree of tolerance and habituation to tobacco is subject to considerable individual variation. Third, the habitual user of tobacco experiences a certain pleasure, a reposeful euphoria or a pacification, which favors digestive activities as long as the limit of tolerance is not too closely approached. Fourth, it should be remembered that in any particular person the functioning of one of the bodily systems may be affected more than another.

In view of the development of some tolerance to tobacco, it is not surprising that many chronic smokers, when they smoke their ordinary number of cigarettes, manifest no significant changes in the activities of the stomach and colon. When the limit of tolerance is approached, it should be expected that the activities of these organs will be influenced. The activity of the stomach tends to be depressed and that of the colon to be stimulated. Hunger motility is the activity of the stomach most readily and uniformly depressed by smoking. Of course depression of gastric motility as the limit of tolerance is reached may cause gastric retention accompanied by a relative hyperacidity. But in only two of our sixty human subjects did we observe an increase in acidity or a gastric retention of any significance when they smoked to the extent that the symptoms of nicotine intoxication were not produced.

Because the usual effect of smoking, when it has an effect, on gastric activity is depression, it does not necessarily follow that all persons will so respond. For example, the stomach of an occasional subject as the limit of tolerance is approached may show that type of vagal hypermotility which precedes the act of vomiting. Or, if the vomiting center has been

sensitized by hunger or the unpleasant taste of a barium sulfate meal, smoking may cause a vagal type of hypermotility of the pyloric antrum.

It should be mentioned that some of the apparently deleterious effects of tobacco smoking in some patients with gastrointestinal complaints may be secondary to cardiovascular disturbances. In some subjects tobacco smoking causes rather marked peripheral vascular changes. Although small doses of nicotine enhance

the excitability of the vomiting center, Hatcher<sup>11</sup> has expressed the belief that nicotine given intravenously reflexly provokes emesis by a peripheral, probably a cardiac, action. This was emphasized by the three patients with ulcer who after smoking two or three cigarettes vomited the tube and fainted. They knew and so informed us that their tolerance to tobacco was less when they had not eaten breakfast. In this connection it is known that hunger sensitizes the mechanism of nausea and vomiting,<sup>12</sup> but the effect of fasting per se on cardiac and vasomotor stability has not been studied.

The profession has available certain rather easily applied tests for determining the effect of smoking on the cardiovascular system. It would seem that those persons who show marked changes in the heart rate, the blood pressure or the peripheral capillary bed in response to smoking should be advised not to smoke. Further, those persons who on smoking have extrasystoles (we had one such subject) or an inversion of the T wave, as recently shown by Graybiel, Starr and White,<sup>13</sup> should be advised not to smoke. Obviously these changes are objective tests for the determination of the deleterious action of smoking on the cardiovascular system of the patient.

When this study was undertaken we had hoped, by using a simple test of gastric function, to find some response to smoking in patients with ulcer which would show objectively and decisively that a particular patient should not smoke. We do not believe that this hope was clearly attained in the case of the patient with ulcer. However, it can be argued that those patients (one of twenty-two) who manifest a definite delay of gastric evacuation on smoking should not smoke. Although we believe that patients with peptic ulcer should be cautioned not to strain their tolerance to tobacco, our results do not indicate that the routine prohibition of the use of tobacco by such patients is necessary. In this regard one cannot rely, apparently, on clinical impressions, because the views expressed vary so widely.<sup>14</sup>

We came closer to attaining our hope in the case of the effect of smoking on the colon. Our results on subjects with presumably normal colons indicate that the prohibition of smoking by patients with any tendency toward irritability of the colon should be seriously considered. This indication will not be established until the effect of smoking on the gastrointestinal and colonic behavior or passage time of such patients has been demonstrated by objective methods. Unfortunately much more effort and time are required to show objectively and decisively that smoking may or may not have a deleterious effect on the colon than to make the same demonstration on the cardiovascular system.

#### SUMMARY

Smoking reflexly stimulates the secretion of saliva in most subjects. It reflexly inhibits or depresses the hunger motility of the stomach. When the smoking of an ordinary number of cigarettes has any effect on the stomach, it tends to depress secretion and to retard evacuation. Only in the occasional person does

smoking tend to cause significant gastric retention and an increase in acidity. Smoking tends to augment the motility of the colon. Smoking affects the secretion of bile and pancreatic juice only when marked alterations in blood pressure occur. As a person approaches his limit of tolerance to tobacco, undesirable changes occur in the activities of the alimentary tract. All patients with peptic ulcer or with colonic disturbances who smoke should be cautioned regarding the undesirable effects of straining their tolerance to tobacco. None of the data we have obtained can be interpreted as directly indicating that smoking has a beneficial effect on the activities of the alimentary tract.

#### ABSTRACT OF DISCUSSION

DR SIDNEY A. PORTIS, Chicago. Some years ago German investigators brought out the idea that the increase of duodenal ulcer in women was associated with their increased addiction to tobacco. Many physicians have observed that patients who have a recurrence of ulcer symptoms when not on management have been habitual users of tobacco, however, it is difficult to evaluate whether this recurrence would not have taken place in the absence of smoking, because it is known that many patients have a recurrence in spite of what is done. I presume that the authors' patients all are on ulcer management during the period of observation, and on such management it is difficult to detect the results of the effects of tobacco. I should like to ask whether they have any evidence on patients during the quiescent period of ulcer who on return to smoking have had a recurrence of symptoms. Further, have there been appreciable differences in the secretory and motor activity of these patients when they began again to use tobacco? If smoking inhibits the hunger contractions and, therefore, lessens the appetite in patients, may then not the lessened desire for food in turn lessen neutralization of gastric secretion and in turn be a factor in the continuance of the ulcer picture? If the neutralization of gastric secretion is an important factor in the life cycle of an ulcer, it would be logical to conclude that the lessened hunger contractions might prolong the period of active ulceration, further, if gastric evacuation is inhibited and pyloric closure lengthened, smoking may be detrimental to an ulcer patient. The results reported today regarding the movements of the colon are interesting, however, the effect of tobacco on the nervous system as a whole may in turn produce variable manifestations in colonic movements, just as the colon may mirror other extracolonic stimuli. I have seen patients who have had constant constipation from the use of tobacco. Further, Drs. Schnedorf and Ivy show in their small group of patients that the smokers had a tendency to hyperacidity more often than the nonsmokers. It is well known that hyperacidity may predispose to constipation. Many clinicians recommend the gradual withdrawal of tobacco. I believe that if tobacco is to be eliminated it should be stopped abruptly. One must use common sense in directing patients in the use of tobacco. If it is felt that an occasional cigaret is not harmful and that the symptoms do not warrant abstinence, one might as well treat the patient as well as the disease.

DR ANDREW C. IVY, Chicago. The German evidence referred to by Dr. Portis was evidence of this type. During a certain period of several years, the incidence of duodenal ulcer or peptic ulcer increased in Germany so many per cent and during that same period the consumption of cigarettes increased so many per cent. That is like most of the evidence that one finds in the literature with regard to the effect of smoking on the alimentary tract. It doesn't mean anything at all, it is not evidence. All of our patients were on ulcer management. Of course, it is generally reported by smokers at large that the excessive smoking of cigarettes decreases their appetite and that they will lose weight if they smoke too many cigarettes. That may be a factor, as pointed out by Dr. Portis. Six of our twenty subjects smoking was a part of the stool habit. In three of them smoking was necessary in order to defecate daily. In three others smoking was necessary in order for the bowel movement to be complete. Now of course that is simply a psychic effect. One can do other things, for example, one can drink a glass of water

before stool, and that will become a psychologic factor in the stool habit. In this evidence that we have brought forward we have not taken into consideration the effect of smoking on the central nervous system. Nervous states affect the activities of the alimentary tract. We pointed out that three of our patients who smoked on an empty stomach collapsed, indicating that the effect of smoking on the cardiovascular system of some subjects is very important and, as shown by Dr. Bishop, cardiovascular disturbances may produce gastrointestinal disturbances. Smoking reflexly stimulates the secretion of saliva in most persons. It reflexly inhibits or depresses the hunger motility of the stomach. When the smoking of an ordinary number of cigarettes has any effect on the stomach, it tends to depress secretion and to retard evacuation. Only in the occasional person does smoking tend to cause a significant gastric retention and an increase in acidity. Smoking tends to augment the motility of the colon. Smoking affects the secretion of bile and pancreatic juice only when marked alterations in blood pressure occur. As a person approaches his limit of tolerance to tobacco, undesirable changes occur in the activity of the alimentary tract. Patients with peptic ulcer or colonic disturbances who smoke should be cautioned regarding the undesirable effects of straining their tolerance to tobacco. None of the data that we have obtained can be interpreted as directly indicating that smoking has a beneficial effect on the activity of the alimentary tract.

## MEDICALLY SUPERVISED VACATIONAL MIGRATIONS

CHARLES I. SINGER, M.D.

LONG BEACH, N. Y.

Huge seasonal migrations take place in the United States every year with apparent regularity and with constantly growing volume. More than 35,000,000 people take part in these migrations, using all means of transportation and spending the incredible but carefully estimated sum of \$5,000,000,000 yearly. These migrations are not studied from a medical point of view nor are they directed or supervised. They lack a conscious, well recognized purpose and are governed mostly by vogues, whims and fads born out of hearsay evidence. The public might derive optimal health benefits from these migrations but never will unless the medical profession will recognize and develop the enormous possibilities lying dormant within them.

The following data on the five important factors of these migrations were collected by inquiries to state health, conservation and highway departments.

1 *Seasonal Characteristics*—The greater portion (about 70 per cent) of the migrations take place in the summer, about 20 per cent in the winter and about 10 per cent in the fall and spring.

2 *Geographic Data*—Inhabitants of all forty-eight states take part in the migrations, but there is a distinct predominance of the northeastern and midwestern states. Typical vacation states are (a) New England, New York and New Jersey, (b) Florida and the Gulf states, (c) California, (d) the Great Lake states and (e) the desert states (New Mexico, Arizona and Colorado).

3 *Geologic Milieus*—The milieus most popular are, in the order mentioned, (a) seashores, lakeshores, (b) altitudes and (c) deserts.

4 *Duration of Stay*—Tourists staying less than ten days within a state constitute about 65 per cent of the migrants. Vacationists, staying more than ten days within a state, constitute about 35 per cent of the migrants.

5 *Distance Covered*—Interstate migrations (a) long distance migration, which is typical with tourists in summer and vacationists in winter, and (b) short distance migration by vacationists in summer. Intrastate migrations—very short vacational migrations within a state, usually in the summer, for instance from valley to mountain and from inland to seashore.

### MOTIVATING FACTOR

The instinctive motivating factor of these mass migrations is the drive for a climatic change. Climate is a long range view of weather in a given locality. Based on broad biologic effects, climates may be divided into two general groups, (1) sedative and (2) stimulating.

The sedative climate is characterized by stability of weather—by insignificant fluctuations of temperature, barometric pressure and humidity by the lack of winds and storms. The stimulating climate is characterized by sudden and wide atmospheric fluctuations. While one considers the Northern climates generally as stimulating and the Southern climates as sedative, one must consider the element of relativity. This can be illustrated with three types of persons: (1) the New England fisherman, (2) the New York business man and (3) the Florida farmer. Each one of these is healthy in his own environment. The late fall climate of North Carolina will be stimulating to the Florida farmer and sedative to the New York business man. The New York business man will find the fall climate of Maine stimulating, while the New England fisherman, accustomed to drenching waves and strong winds, will find it mild. The migration to a less stimulating climate may be called "the escape." The migration to a more stimulating climate may be called "the challenge."

### CLIMATIC SEDATION

The climatic sedation, "the escape" from the hardships of winter, is a good protective therapeutic measure. Its chief indications are: 1. Constitutional (a) for the feeble aged and (b) for the delicate child. 2. Debilitating diseases, such as (a) rheumatic heart disease, (b) chronic nephritis and (c) rheumatoid arthritis.

### CLIMATIC STIMULATION

The exposure to a more stimulating climate starts a slight disturbance in the system. Marked and typical fluctuations in the blood cell count and in the blood chemistry can be observed, and parallel changes in the basal and mineral metabolism occur. Thus the organism immediately attempts to correct by mobilization of its interrelated forces of defense, neurovascular, hematogenic, chemical and endocrine. By successive exposures the amplitude of these climatic microdamages decrease as the acclimatization progresses. Parallel with the process of acclimatization, preexisting chronic disorders may be overcome with the same systemic effort.

While climatic stimulation has its definite zone of contraindications, it is indicated whenever stimulation of the hemopoietic organs, a higher basal and mineral metabolism, increased depth of breathing or more vigorous physical heat regulation is deemed necessary in preventing or treating disease.

The chief requisite of successful climatic therapy is to find the optimal amount of climatic stimulation. There is an ineffective underexposure to climate and a harmful overexposure. The optimal amount of exposure, the therapeutic dose, varies with (1) the

season and climate selected, (2) the condition, constitution and age of the patient and (3) the nature and stage of chronic disorder to be influenced

The three main forms of climatic therapy are (1) plain climatic change, (2) selective utilization of climatic factors (sunning, bathing, open-air exposure) and (3) use of climate as a background in special types of therapy, such as mud treatments for arthritis, carbon dioxide baths for cardiovascular diseases and inhalation therapy in chronic bronchial conditions

The average American is not chiefly concerned with improving his state of health during his vacation. His conscious motives are wanderlust and the craving for a good time. He fulfils his desires in this respect but neglects his chance to improve his physical condition at the same time. It is different with the European. Based on ten years of European medical activity devoted to the study of health resorts and to treating chronic sick, it is safe to say that, of a hundred chronic sick Europeans visiting continental health resorts, seventy-five or more are sent there by the family physician or by a consultant. During their stay, they are under the supervision of the spa physician. It is traditional with the European to take his vacation regularly and to consider it to be a very important constructive period of life. Whether he feels ill or not, he consults his physician about the site of his vacation. If he suffers from a chronic disorder, he prefers to be sent to the peaceful atmosphere of a health resort with medical supervision where, removed from home environment, taken away from his phobias and idiosyncrasies, he devotes his time to "the cure," which involves an emotional readjustment as well as a somatic rehabilitation. This emotional armistice and the shedding of faulty habits of living are just as essential to the future welfare of the chronic sick as the sedative or stimulative climatic factors of baths, packs and drinking cures. Whereas the European vacation is medically directed and supervised, the American vacation is undirected.

The pitfalls of undirected mass migrations may be grouped as (1) qualitative (a) faulty selection of the place of vacation, (b) disregard for climatic contraindications and (c) continuation of faulty habits of living during the vacation, as in eating, clothing and sleep, (2) quantitative (a) too short a vacation, (b) insufficient utilization of climatic factors, (c) over-exposure to the climate with consequent reactions and (d) excessive activity during the vacation. These mistakes are due mainly to the fact that the migrations are ungoverned, are undirected from start to finish and lack a planned health program. The American public does not know that for the healthy individual a medical vacation guidance is advisable and that in the sick it is imperative. People should be taught to know this.

#### COMMENT

It would be inadvisable to transplant European methods of treatment and medical economics to our country. It would be short sighted, however, to fail to exploit some of the conclusions of centuries of empirical continental medicine. A bigger mistake would be to leave unnoticed the results of painstaking analytic research in the biology of European climate. No doubt the handbooks of European balneology and climatic therapy place too much importance on technical detail, offering too many hydrotherapeutic prescriptions. However, many of their institutions have

survived the test of time and of modern biologic research. Some of these valuable assets of Europe are

- 1 The congenial scientific cooperation between the family physician and the spa practitioner in exchanging information about the patient

- 2 The compulsory medical examination, supervision and thorough case history in scores of European spas

- 3 The forty seashore sanatoriums for underdeveloped, sickly children on the 40 miles of seashore of Belgium

- 4 The biological climate research stations in Bad Elster and in Wyk on Fohr, operated by the universities of Hamburg and Leipzig

- 5 The cooperation of the state, railroads, utilities and charitable funds in maintaining several thousand beds in sanatoriums built in spas and health resorts for chronic sick children and adults in France

- 6 The handling of the chronic sick and convalescents of the state workers' insurance institution of Hungary

- 7 The national committee for exploring mineral waters and muds in Austria

- 8 The Harrogate Spa Booklet and the Spa Register of England

Health resorts in specific climatic locations may become the ideal migratory goals of the medically supervised mass vacationing of the future. The present situation of the American health resorts is somewhat discouraging. There are only a dozen of the first order. They necessitate travel of several hundred miles from some parts of the country. Less than 1 per cent of the migrators select them as vacation grounds. Nearly all of them have shown a decline of patronage in the last few years. This decrease of patronage is due partly to economic causes but mostly to lack of physicians' interest, because of lack of reliable information in the literature concerning spas, lack of medical supervision in spas and unfounded claims in spa booklets. Our health resorts are real national assets. They should multiply in number, as they are indispensable in the care of the chronic sick.

The chronic sick of America consist of the real forgotten people. These hundreds of thousands who cannot find help in surgery and do not respond to medication are considered the *crux medicorum* by the general practitioner. They start their vacation with insufficient medical advice or no advice at all. If they can afford to stay at a medically supervised health resort they will receive care, but this is not within the reach of the major portion of our migrants. In resorts lacking a well organized medical institution the general practitioner is too busy during the vacation season. He can devote sufficient time neither to the chronic sick nor to the study of the effects of his climate. He finds it difficult to answer the many questions asked by the bewildered vacationist. He should be able to answer them with scientific certainty, but the basic facts are not yet established. Undirected, they accept whatever is offered. No wonder they fall prey to quacks, charlatans and cultists, who follow them like vultures.

To develop the modern American climatic therapy, the following steps seem to be important: (1) an inventory of our natural resources, (2) development of institutions and (3) education of (a) a new type of specialist, (b) the general practitioner and (c) the public. Nature did not bestow all its natural resources on Europe. On the contrary, Europe has no Florida,

California, Nevada or Colorado and nothing like Yellowstone Park, with its mineral thermal springs and mud volcanoes. America is fortunate to find within its boundaries an array of specific climatic types, all types of seashores from Nordic to subtropical, high altitudes and deserts. But the biologic effects of our different climatic types have to be evaluated. Our thermal mineral springs, muds and moors must be standardized, indications and limitations must be determined, unwarranted claims must be weeded out.

The American Medical Association has a committee on spas and health resorts. This committee has a tremendous job. To be efficient, it should be supported by state committees and interstate special field committees.

The medically supervised health resort is the logical place to care for the vacationist properly. A health resort should be characterized by (1) the presence of natural resources with therapeutic value, (2) suitable physical facilities for administering the natural therapeutic agents, (3) competent medical supervision and medical records and (4) provisional facilities for research work.

The development of American health resorts should not follow a plan of imitating completely those of Europe. The development must be based on our national characteristics, type of resources and standards of living.

#### INSTITUTIONS

1 *Physical Therapy Institution*—The institution most needed for the development of this problem is a type which would fully utilize the natural resources of a given place, especially equipped for diagnosis and modern physical therapy. This type of institution would take care of the ambulatory chronic sick patient and the healthy vacationist in need of medical advice.

2 *Sanatorium*—Another type of institution needed is the sanatorium devoted to the care of diseases beneficially influenced by the local climate. Sanatoriums should be built on seashores, deserts and forests, in high altitudes and in valleys with southern exposure. These sanatoriums would serve chronic patients in need of the effect of certain climates and of constant medical supervision.

3 A climate research station and a biologic research laboratory will be indispensable in the future concept of a health resort. They can be coupled with either the physical therapy institution or the sanatorium. The staff of these institutions should consist of general practitioners who are specialists in physical therapy and climatology and specialists in other fields as the need for them arises.

A well equipped general hospital is a necessity, independently from the health resort problem.

#### EDUCATION

Physical therapy in its broad aspects of electrotherapy, hydrotherapy, mechanotherapy, climatology, with their extensive ramifications is too big a problem for a general practitioner as a postgraduate study if he is not prepared in the fundamentals in his undergraduate years. He cannot acquire a good background in the subject during working years in practice by nibbling on fragments here and there in abstracts of foreign articles.

A new type of medical specialist will be needed in American health resorts if the vacationist will be directed to the spas. In the mind of this new type of

spa specialist, or climate therapist, the knowledge of all branches of physical therapy should be blended with all other scientific information essential to general practice. He must be acquainted with the problems of heredity and constitution, as his main job will be to influence constitutional factors in chronic disease. He must know psychotherapy and medical climatology.

Physical therapy should be taught in our universities, and the teaching of it should start in the preclinical years. The courses could be molded into physiology and therapeutics. In the clinical years the effect of physical therapy in disease should be taught. Introduction to the problems of climatic therapy and spa medicine with field trips to spas and health resorts is the routine to follow. A required graduate training of at least three years' internship should precede the recognition of a specialist in physical therapy. The first year should be spent in a general rotating internship, the second year in specialized sanatoriums or hospitals located in reputable health resorts and approved for the purpose of internship by the American Medical Association, the third year to be divided among the different health resorts in the United States to obtain a comprehensive view of the field in which he is to specialize.

#### THE GENERAL PRACTITIONER

The general practitioner is an important link in this new field of medical endeavor. His cooperation is one of the main pillars of success of this crusade. He can be reached only by postgraduate courses, lectures in his county societies, hospital staff meetings and medical periodicals. Organized excursions to leading health resorts should be planned for general practitioners regularly, to get them acquainted with the work.

#### THE PUBLIC

Every means of conveying information should be used to inform the public about the benefits of medically supervised vacationing. (1) lectures given by leading medical men in clubs, schools, social organizations and health resorts, (2) newspaper campaigns, (3) movie shorts, (4) scientific pamphlets on health resorts and (5) courses on hygiene in high schools and colleges.

#### BENEFITS

Who will benefit by this new field of medical activity?

A *The Public*—The chronic sick belong in spas during their vacation. In the suitably selected climatic background of the spa, spurred by or protected from climatic stimulation, they can be guided in a systemic rehabilitation in habit reforms and in emotional readjustment. For the healthy vacationist, an individually planned vacation, molded to personal requirements, is an important link in the problem of keeping fit. Through careful planning of the hygienic aspects of the migrations, which is partly an interstate problem, reductions in epidemics will ensue and experience will be gained useful in other aspects of public health.

B *Medical Science*—Through penetration into these unexplored medical fields, future possibilities of scientific progress will arise. New biologic facts may be revealed. New methods of treatments will be found.

C *The Medical Profession*—The general practitioner gains a closer contact with the patient in planning his vacation and will enjoy scientific cooperation with the spa practitioner instead of losing his undirected patient to cultists and charlatans. Whether young medical men will find future satisfaction in the field

of American climatic therapy depends mainly on the strength of the leadership displayed in developing this complicated set of problems

**D The Health Resorts**—Since reputable health resorts are the most logical places for medically supervised vacationing of both ailing and healthy, they will be the first to reap the benefits

#### SUMMARY

1 An estimated 35,000,000 people take part in undirected seasonal vacational migrations in America

2 They are confronted with a climatic change, stimulating or sedative, which if properly selected can be utilized in preventing and influencing disease

3 A comparison of Europe and America shows that the health-promoting natural resources of the former are far more effectively developed than those of this country

4 The chronic sick as well as the healthy vacationist would greatly benefit by individually planned, medically supervised vacationing, preferably in a health resort

5 A comprehensive plan embodies suggestions for the development of American climatic therapy

7 The plan will benefit the American public, medical science and the medical profession at large

## Clinical Notes, Suggestions and New Instruments

### PENETRATION OF TISSUE BY GREASE UNDER PRESSURE OF 7000 POUNDS

F HILTON SMITH M.D. SALINAS CALIF

The increasing use of high pressures in industry undoubtedly will result in many accidental penetrations of tissue by foreign materials. A case of destruction of a finger by fuel oil ejected from a Diesel engine has been reported in *THE JOURNAL*.<sup>1</sup> The present case concerns a more widespread hazard as the type of lubricating mechanism involved is becoming common

#### REPORT OF CASE

J W, an automobile mechanic aged 31, was lubricating the springs of a passenger car with a device which ejects grease from a hollow needle inserted into grease fittings. His right hand which held the "gun" slipped, and the needle barely touched the skin at the volar base of the left index finger. The valve automatically tripped and grease with an asphalt base under a pressure of 7000 pounds was forced into the finger. The digit immediately became numb, and the patient felt weak and faint. A half hour after the accident the objective signs were not marked. There was little swelling of the finger or hand motion was unimpaired and painless and the only visible injury was a small wound just above the proximal crease of the left index finger. Through this opening about a drachm (4 cc) of thick clean grease was expressed. Since the patient's hands were covered with road dirt at the time of the accident tetanus antitoxin 1,500 units, was given immediately and he was instructed to apply compresses of hot magnesium sulfate solution. Twelve hours later the finger and hand were slightly swollen although not tense or edematous. The epitrochlear and axillary nodes were not enlarged or tender. The temperature was 98.2 F. The pain however, had become so intense that use of opiates was necessary. The patient was sent to the hospital where a blood count revealed 92 per cent hemoglobin 4600 000 erythrocytes and 8000 leukocytes with 81 per cent poly-

morphonuclears, 15 per cent small lymphocytes, 3 per cent large lymphocytes and 1 per cent mononuclears

The urine was acid and its specific gravity 1.024, there was no albumin or sugar. Microscopic examination showed a few squamous epithelial cells, one or two pus cells per high power field and an occasional erythrocyte

Nitrous oxide anesthesia was administered and lateral incisions made through the pulp of the finger at the middle and proximal phalanges. About a half ounce (15 cc) of grease was expressed from the finger and milked down from the palm of the hand. After this the hand was elevated and magnesium sulfate compresses were applied. These were continued for the next five or six days and on two occasions the hand was saturated with ether in an attempt to dissolve the remaining grease. Roentgenograms taken at this time showed no bony involvement

Despite the fact that wide incision had been done before the onset of any considerable edema, moist gangrene of the finger developed on the fourth postoperative day. The epidermis overlying the entire finger became loosened and the gangrenous portion beneath showed small beads of grease oozing from the

Fig 1—Moist gangrene of finger ten days after the accident. The point of entrance of the grease was just above the proximal edge of skin

intensely red moist surface. This tissue peeled off in layers and was saturated with grease. Dry heat was applied, and the distal and middle portions of the finger soon became dehydrated into oily masses of insensitive tissue. The skin overlying the proximal phalanx and metacarpophalangeal joint became raised in large blisters and the underlying tissue showed the same intensely red oily appearance noted more distally. On the ninth day after admission metacarpophalangeal disarticulation was performed and the flaps of skin left open. At the time of this operation the palmar space was probed. With but few objective signs to indicate its presence, an ounce (30 cc) of grease was milked down from this space and an additional half ounce (15 cc) was found in the tissues of the wrist. After this operation the temperature varied from 99 to 101 F for four days. The wound healed slowly, small amounts of grease appearing on the dressings for five weeks. Two months after the accident the patient was able to resume work, although there was still transient edema of the hand when he performed hard labor

Pathologic examination of the finger was made by Dr David A Wood. Sections taken through the soft tissues showed numerous subcutaneous abscesses infiltrated by myriads of polymorphonuclear leukocytes. There was considerable necrosis of the subcutaneous connective tissue. In areas there was much fibroblastic proliferation and giant cells of the foreign body type. Fat stains revealed occasional small droplets of fat along the periphery of the abscesses. The grease itself, as sold, is sterile neutral in reaction and composed of grease with an asphalt base incorporated in a sodium soap. It also contains a small amount of brown oil dye but the quantity is negligible

1 Rees, C. E. Penetration of Tissue by Fuel Oil Under High Pressure from Diesel Engine. *J. A. M. A.* 109:866 (Sept. 11) 1937

and should not be injurious to living tissue. The contamination occurs in the gun itself and the road dirt which covers the fittings of the car.

## COMMENT

The lubricants in use in many stations where automobiles are serviced are forced into grease fittings under pressures ranging

Fig. 2—Lateral view. Tissue beneath the blisters was identical with that of the denuded terminal phalanx.

from 500 to 7,000 pounds. This is a far cry from the familiar grease cup of a decade ago. Few modern grease racks depend entirely on the hand type of gun to force lubricants into spring shackles, universal joints or other parts of the car provided

Fig. 3—Showing dry gangrene of the dorsal surface and the lateral and volar surface.

with fittings. The efficiency of the lubrication depends on satisfactory filling of bearing spaces and to expedite the work tremendous pressures are employed. The air pressure going from the compressor to the lubricants is increased as much as forty times, and a thin stream of grease is forced through a hollow

needle-like ejector into the fitting. Thus a pressure of 140 pounds in the tank (that usually employed) will provide a pressure of 6,000 pounds at the outlet. Grease issuing from the orifice of such a device is a missile capable of causing considerable damage, easily penetrating human tissue. Familiarity of operators with the old style systems has given them a feeling of safety which does not apply to newer, higher pressure lubricating machines. The small opening in the needle which pierces the fitting should be regarded with all the precautions applicable to the muzzle of a loaded rifle.

In the event of accidents of the type just described early and extensive incision is the treatment of choice. It should be borne in mind that even without edema the history of such an injury is just cause for immediate and wide opening of the tissues and attempted expression of the foreign material. It seems possible, however, that with such pressures irreparable damage can take place at the instant of injection.

Bank of America Building

## Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT  
HOWARD A. CARTER, Secretary

### GENERAL ELECTRIC SUNLAMPS ACCEPTABLE

Manufacturer: General Electric Company, 1285 Boston Avenue, Bridgeport, Conn.

The General Electric Sunlamps generate ultraviolet and heat radiation. There is evidence that the ultraviolet radiation produces vitamin D in the body, which has a favorable influence on the metabolism of calcium and phosphorus in general and the prevention of rickets in particular. These sunlamps come in three models, Miami BM3, California BM7 and Florida BM6. Each lamp makes use of the S-1 type General Electric Mazda Sunlight Bulb.

The Mazda Sunlight Lamp Type S-1, the source of radiation, may be described as a combination of tungsten electrodes in parallel with a tungsten filament. These are enclosed in a special glass bulb along with a little pool of mercury. The current first flows only through the filament but, as the temperature increases, the mercury vaporizes and an arc is formed between the ends of the tungsten electrodes. The process requires only a few seconds, although a few minutes is required for the lamp to begin radiating ultraviolet energy at its maximum efficiency. The mercury arc between the electrodes produces the major portion of the effective ultraviolet radiation. The result of the combination produces radiations in the visible and the infra-red as well as in the ultraviolet zones. The bulb is made of Pyrex glass, which absorbs most of the radiation in the ultraviolet region shorter than approximately 2,800 angstrom units.

These lamps operate only on alternating current. Type S-1 requires an input of 450 watts. The lamp stands are equipped with special transformers in the base to secure the proper voltage, since the S-1 bulbs do not fit in the ordinary lamp socket.

The General Electric Sunlamps generate 50 microwatts per square centimeter at a distance of 45 inches from the rim of the reflector. At this distance a period of sixteen minutes under these lamps is equivalent to twenty minutes under midsummer sunshine. A minimum perceptible erythema may be produced at a distance of 45 mm in twenty minutes on the average untanned skin.

Based on the evidence that radiation from the Mazda Sunlight Lamps Type S-1 may produce a minimum perceptible erythema at the prescribed distance, are prophylactic for rickets and play an important role in tooth formation and maintenance of normal structure, the Council on Physical Therapy voted to include the General Electric Sunlamps Models Miami BM3, California BM7 and Florida BM6 in its list of accepted devices.

General Electric Sunlamp BMJ 5

# HOSPITAL SERVICE IN THE UNITED STATES

## EIGHTEENTH ANNUAL PRESENTATION OF HOSPITAL DATA BY THE COUNCIL ON MEDICAL EDUCATION AND HOSPITALS OF THE AMERICAN MEDICAL ASSOCIATION

A number of records in hospital service were broken in 1938, as revealed in the Annual Census of Hospitals just completed

The number of registered hospitals increased over that of the previous year for the first time in eight years, births in hospitals went over the million mark, the number of beds increased 36,832, a figure well above the average annual increase of 24,677 beds a year for thirty years, from 1909 to 1938 inclusive

Hospitals admitted patients in 1938 at the rate of one every 33 seconds

There are 6,166 hospitals, 1,161,380 beds, 56,747 bassinets, 1,026,771 births, 965,706 average census and 9,421,075 patients admitted

In addition to the 6,166 hospitals registered, 136 are opened and their registration is pending, sixty-seven

patient days in general hospitals numbered 106,897,550, or 30.3 per cent of the total

The 4,286 general hospitals admitted 8,545,930 patients, or 90.7 per cent of the total admissions to all registered hospitals, and the average length of stay of patients in general hospitals was 12.5 days

In 1938 the average daily census increased 21,270, the number of empty beds increased 15,562 and the number of empty general beds increased 8,643

The rate of occupancy in general hospitals was 68.9 per cent of capacity

### BED OCCUPANCY IN HOSPITALS

The average census of 965,706 patients in all registered hospitals left an average of 195,674 idle beds. The number of idle beds had been around 180,000 dur-

### SUMMARY OF HOSPITAL DATA

	Number	Beds	Bassinets	Patients Admitted in 1938
1 Registered hospitals and sanatoriums approved for internships, residencies and fellowships	986	409,768	25,659	4,960,053
2 Other hospitals, sanatoriums and related institutions, registered	5,180	751,612	31,088	4,461,022
Total registered	6,166	1,161,380	56,747	9,421,075
				Number
3 Refused registration after investigation (capacity 18,372)				636
4 Unclassified emergency stations, clinics, offices, cottages, and so on, with bed care (capacity unknown)				2,529
5 Prospective hospitals and sanatoriums				
a Opened Registration pending				136
b Under construction				67
c Planned Construction pending				185

are under construction and 185 are planned and being developed

The rate of growth in registered hospitals was equivalent to one hospital of 101 beds for each day in the year 1938, Sundays and holidays included

Governmental hospitals were responsible for 71.6 per cent of the total increase in beds in 1938 and for 89.5 per cent of the increase in 1937. Nongovernmental beds increased 3.1 per cent over the previous year, while governmental beds, federal, state and local, increased 3.3 per cent

Bassinets increased 1,181 in 1938, and 93,859 more births were reported for 1938 than for 1937

One person in fourteen became a hospital bed patient during the year 1938, according to the population as estimated by the United States Bureau of Census July 1, 1938

The figures for patients admitted and average daily census of patients throughout this article are exclusive of newborn infants and do not include outpatients

Patient days in all hospitals aggregated 352,482,690, a gain of 7,763,550 over the preceding year. The

ing recent years. In general hospitals there were 132,454 idle beds as compared with 123,811 in the preceding year. Even in nervous and mental hospitals the average number of empty beds increased during the year from 23,710 to 29,485, although need for more mental hospital facilities is obvious in most states. Idle beds in tuberculosis hospitals were reduced from 11,951 to 9,780. The average number of unoccupied beds in governmental hospitals for the year was 78,449, a considerable increase over 69,869 for the previous year. Occupancy of church hospitals fell from 68.6 per cent to 67.4 per cent, showing their average daily number of idle beds to be 38,945. The idle beds in nonprofit hospitals averaged 91,367 and in all nongovernmental hospitals 117,225

The compilations on these pages show too clearly to justify repetition in the text the percentages of beds occupied in all kinds of hospitals, grouped according to control and to type of service, for the years 1929, 1933, 1937 and 1938, also the average number of unoccupied beds in hospitals grouped in a similar manner for the years 1929, 1937 and 1938

While the past year was characterized by increased use of existing hospital facilities, this increased occupancy has not kept pace with the building program, by which there was a net increase of 36,832 beds

HOSPITAL FACILITIES AS SHOWN BY THE  
ANNUAL CENSUS

For a knowledge of hospital facilities in total, attention is invited to the summary of hospital data on the opening page of this article and to the totals of the

Percentage of Beds Occupied

	1929	1933	1937	1938
According to Ownership or Control				
Federal	76.8	70.0	52.5	51.8
State	94.6	94.5	90.5	94.7
County	80.7	80.8	88.1	8.1
City	74.3	83.0	81.8	81.1

Convalescent and rest	70.9	69.2	71.2	73.6
Hospital departments of institutions	63.0	60.1	66.4	67.0
All other hospitals	74.6	79.3	58.1	64.7
Total all hospitals	80.1	78.8	84.0	83.2

columns in table 1 and table 2. The total number of registered hospitals is now 6,166 as compared with 6,128 one year ago. This is the first time since the annual census of 1930 that the number of registered hospitals was greater than for the preceding year. The total number of beds available in all registered hospitals is 1,161,380, or an increase of 36,832 over last year. Bassinets now number 56,747, or an increase of 1,181 over last year.

Those registered hospitals which have been approved for internships, residencies and fellowships now number 986, their total capacity is 409,768 beds and 25,659 bassinets. Furthermore, they admitted 4,960,053 patients, or 52.6 per cent of total admissions to all registered hospitals.

The hospitals which after investigation were refused registration number 636 with a capacity of 18,372 beds and 2,131 bassinets.

Regarding the hospital facilities for the future, a healthy expansion is indicated by reports received from 136 hospitals which are open but for which there has not been time for investigation and registration. Sixty-seven new hospitals are known to be under construction and another 185 have been planned and are being

developed. In addition to the hospitals listed and those being developed there are numerous facilities which for want of a better term are called "unclassified," including emergency stations, clinics, offices, cottages and so on, with facilities for bed care and nursing along with the medical care. Records in the office vouch for the existence of 2,529 of these auxiliary institutions.

CHANGES IN GOVERNMENTAL HOSPITALS  
DURING THE YEAR

There are now 1,728 governmental hospitals in the register as compared with 1,722 a year ago, an increase of six. The total capacity of all registered governmental hospitals is 815,136. There is a slight decrease in the number of bassinets.

Federal institutions increased in number but reported slightly fewer beds. The state hospitals number 523, one more than a year ago, and their capacity has increased from 508,913 to 541,279.

The mental hospitals were asked to report their rated capacity. In the figures on mental hospitals published in 1937 for the year 1936 and in 1938 for the year 1937 there were special data on the rated capacity of state mental hospitals. There is being prepared for publication a special report on mental hospitals which will comment at length on the extent of hospital facilities, their rate of occupancy and their status of overcrowding.

Both the number of county hospitals and their bed capacity increased in the past twelve month period, but there was a marked decrease in the number of bassinets provided in county hospitals. City hospitals declined both in number and in capacity. City-county hospitals increased with respect to the number of hospital number of beds and number of bassinets.

Analysis of General Hospitals by Control

	Hospitals	Beds	Bassinets	Patients Admitted	Average Census
Federal	260	47,706	767	397,116	6,112
State	52	17,332	916	298,667	11,671
County	210	29,664	2,238	466,590	22,228
City	220	46,343	4,063	866,306	36,132
City county	8	5,883	507	191,310	8,863
Total governmental general	740	147,350	8,513	2,100,189	11,614
Church	833	107,739	16,140	2,481,907	71,191
Fraternal	10	1,176	104	17,444	1,011
Associations and restricted corporations	1,329	128,190	90,739	2,938,592	3,067
Total nonprofit general	2,197	237,095	37,013	5,483,173	15,770
Individual and partnership	947	29,360	4,962	461,446	10,177
Corporations (unrestricted as to profit)	362	18,514	3,136	431,022	10,250
Total proprietary general	1,309	40,874	7,398	892,568	9,067
Grand total general hospitals	4,286	420,374	52,924	8,040,900	9,970

The returns from nongovernmental hospitals show an increase in number from 4,406 to 4,438, in beds from 335,799 to 346,244 and in bassinets from 46,644 to 47,636. Church hospitals showed considerable growth for the year both in number and in capacity, as did all nonprofit corporations and associations and those run by individuals and partnerships. However, the corporations unrestricted as to profit, or frequently referred to

as corporations for profit, continued their downward trend from 530 to 493 in number and from 28,085 to 26,550 in capacity

#### CHANGES DURING THE YEAR IN HOSPITALS BY TYPE OF SERVICE

As usual, the general hospitals outnumber those of any other classification. We now find a total of 4,286 registered general hospitals as compared with 4,245 last

#### How Hospitals Shared in Patients Admitted

	Number of Patients Admitted		Share (per Cent) of All Patients Admitted	
	1931	1938	1931	1938

Isolation	40 010	34 017	0.6	0.4
Convalescent and rest	20 678	36 260	0.4	0.4
Hospital departments of institutions	131 291	142 714	1.8	1.5
All other hospitals	30 604	36 160	0.5	0.4

year. For the same period there has been a net increase of 13,233 beds in general hospitals and 1,256 bassinets.

The nervous and mental hospitals show a marked increase both in number and in capacity, and the same is true of maternity, children's, and convalescent and rest hospitals. There is a slight decrease in the number of tuberculosis, industrial, eye, ear, nose and throat and isolation hospitals and in the number of institutional hospitals.

#### Summary of Growth of Hospitals 1909 to 1938

Year	Federal Hospitals		State Hospitals		All Other Hospitals		Total	
	Number	Capacity	Number	Capacity	Number	Capacity	Number	Capacity
1909	71	8 827	232	189 049	4 006	220 189	4 309	421 065
1914	93	12 609	294	232 834	4 600	287 040	5 037	532 481
1918	110	18 810	303	262 204	4 910	331 182	5 323	612 201
1923	220	53 869	601	402 206	6 009	399 640	6 830	705 722
1928	294	61 760	590	369 709	5 963	461 410	6 847	892 964
1931	291	69 170	576	419 282	5 746	480 663	6 613	974 110
1932	301	74 101	608	442 601	5 693	497 602	6 602	1 014 304
1933	300	70 630	557	439 646	5 380	491 765	6 437	1 027 046
1934	313	77 860	544	473 080	5 477	497 701	6 334	1 040 101
1935	316	83 303	526	483 094	5 404	500 792	6 466	1 060 179
1936	313	84 234	524	503 306	5 342	509 181	6 189	1 090 721
1937	309	97 001	522	508 913	5 217	517 654	6 128	1 124 568
1938	330	97 245	523	541 279	5 313	527 803	6 166	1 161 327

More significant than the changes in facilities noted here are the figures showing increase and decrease in the number of patients admitted and the average census of patients in the same institutions. The admissions and patient population are therefore set down by years for ready reference and comparison in table 2.

#### TRENDS SHOWN BY COMPARISON OF 1927 AND 1938

The principal sources of statistics on the entire field of hospital facilities are (1) the various editions of the American Medical Directory and (2) the Hospital Numbers of THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION. The first edition of the directory (1906) contained an incomplete list of hospitals. By 1909, when the second edition was published, a fairly complete list of all the hospitals in the country, eliminating those believed unsatisfactory to print, was published. Each subsequent issue of the directory has contained a revised and fairly complete list of hospitals.

The directory, therefore, was practically the only source of information about all the hospital facilities from 1909 to 1920. In the latter year a beginning was made on the Annual Census of Hospitals and the first

Total unoccupied beds—all hospitals	190 267	180 112	190 674

Hospital Number of THE JOURNAL was published in 1921. The early and middle twenties were a formative period in the development of the annual census and the annual Hospital Number. Improvement was shown in each subsequent Hospital Number of THE JOURNAL.

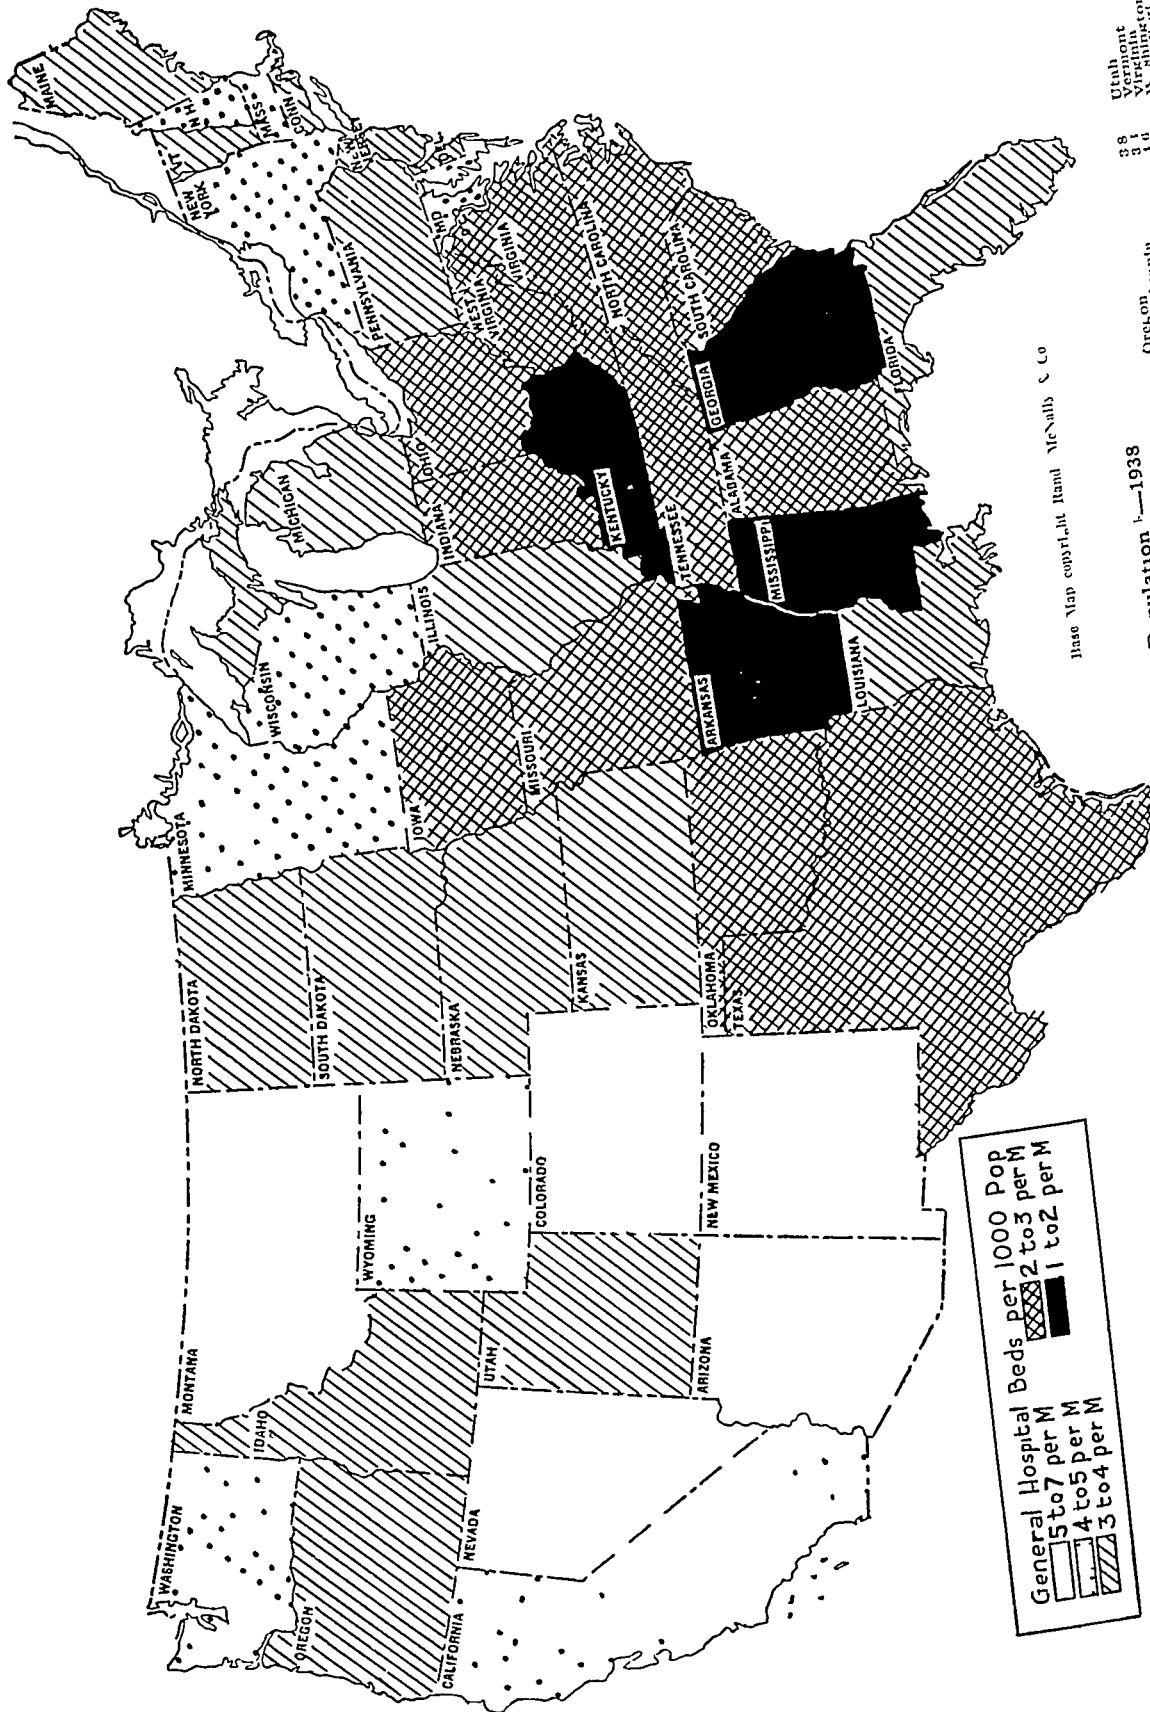

Through patient and courteous contact with hospitals and by persistent effort, asking for only a small amount of information but persisting until the maximum number of hospitals was heard from, the Association by 1927 was enjoying a response to its annual census representing usually more than 90 per cent of all the registered hospitals, and for most years 96 per cent of the hospitals and around 99 per cent of the entire bed capacity.

Therefore from 1927 to 1938 inclusive—eleven years—we are able now to present figures that are believed to be the most accurate available. Some definite trends of hospital development as to types of service and as to ownership or control may be observed.

In the eleven year period we find that the number of hospitals has diminished from 6,807 to 6,166. This

### Occupancy in General Hospitals

The percentages of beds occupied in general hospitals during the year 1938, by states, were as follows

Alabama	69.5	Minnesota	62.9
Arizona	57.0	Mississippi	57.0
Arkansas	78.9	Montana	70.5
California	70.5	Nebraska	56.4
Colorado	72.5	Nevada	58.2
Connecticut	72.4	New Hampshire	62.5
Delaware	73.3	New Jersey	61.4
Florida	62.9	New Mexico	53.0
Georgia	57.0	New York	68.4
Idaho	78.9	North Carolina	58.2
Illinois	69.5	Ohio	62.5
Indiana	67.1	Oklahoma	61.4
Iowa	63.1	Pennsylvania	71.0
Kansas	80.2	Rhode Island	79.3
Kentucky	68.8	South Carolina	63.3
Louisiana	64.6	South Dakota	63.0
Maine	69.2	Tennessee	69.8
Maryland	67.1	Texas	74.1
Massachusetts	63.1	Utah	70.9
Michigan	63.1	Vermont	71.1
Minnesota	62.9	Virginia	68.8
Mississippi	57.0	Washington	65.5
Montana	70.5	West Virginia	63.3
Nebraska	56.4	Wisconsin	62.0
Nevada	58.2	Wyoming	60.7
New Hampshire	62.5		
New Jersey	61.4		
New Mexico	53.0		
New York	68.4		
North Carolina	58.2		
Ohio	62.5		
Oklahoma	61.4		
Pennsylvania	71.0		
Rhode Island	79.3		
South Carolina	63.3		
South Dakota	63.0		
Tennessee	69.8		
Texas	74.1		
Utah	70.9		
Vermont	71.1		
Virginia	68.8		
Washington	65.5		
West Virginia	63.3		
Wisconsin	62.0		
Wyoming	60.7		

reduction in number is due to several factors Among them is a tendency for smaller hospitals to combine with larger ones in the development of city and town hospital systems The reduction is due also in part to increasing strictness with which the Essentials of a Registered

ably reduced in numbers, having fallen from seventy seven to thirty-eight, isolation hospitals from ninety eight to fifty-four, and convalescent and rest from 159 to 121 These same hospitals also showed a falling off in their number of beds and in average census of patients

Without doubt much of the slump in number and capacity of some of the special types of hospitals just mentioned is related to a corresponding increase in the number of patients in the general hospitals We find that, while the general hospitals declined in number from 4,322 to 4,286, at the same time their beds increased from 345,364 to 425,324 and the average census from 228,084 to 292,870

Most striking of all changes, perhaps, is that of nervous and mental hospitals, which increased in number only from 563 to 592 but in bed capacity from 373,364

to 591,822 The average census of mental hospital bounded from 349 667 in 1927 to 562 337 in 1938 In this issue the occupancy figures which are given by years show considerable additions each year to the capacity of mental hospitals and the end of building has not yet come, if we are to judge by the amount of interest and the comparative unanimity of opinion with regard to the need for additional facilities in this particular field

Tuberculosis hospitals were represented by 508 institutions in 1927 and 493 in 1938 The number of beds increased from 63 170 to 76,022 and the average census from 50 784 to 66 242 Additional beds for tuberculosis are available in general and other hospitals as shown in the special report on tuberculosis facilities published in THE JOURNAL, Dec 7, 1935 At that time a total of 95,198 beds available for the treatment of tuberculous patients included 14,468 in general hospitals and 9,478 in nervous and mental institutions Aside from the numerical increase in beds there are indications too that any given quantity of facilities can take care of more patients than formerly because of the

rapid advance in methods of treatment. In the fight against tuberculosis a greater degree of control has been achieved than is claimed in most other fields. A supplementary report on tuberculosis facilities in the United States is now in the process of preparation and will be available within a few months.

The hospital departments of institutions which numbered 530 eleven years ago and number 235 at the

hospitals that fill an indispensable function for the inmates of the institutions which they are designed to serve.

#### GROWTH OF GOVERNMENTAL HOSPITALS 1927 TO 1938

Turning now to find out what increases and decreases have been made in the eleven year period by the different governmental and nongovernmental groups of ho-

present time were designed to take care of the sick inmates in custodial institutions such as orphanages, homes for the aged, prisons and schools. Statistics given here for these institutions are intended to cover the hospital patients and do not include other inmates. The bed capacity of these hospital departments, 21,808 remains practically the same as eleven years ago and the average census of patients has increased from 12,453 to 14,730. The figures obviously indicate just what the institutions themselves report—that most of such departments have been closed and that sick inmates are now hospitalized mainly in general hospitals. Evidently many of the 235 that still persist are well developed

pitals, we find that the total number of governmental hospitals, including federal state, county, city and city county, was 1,809 in 1927 and 1,728 in 1938. This group of governmental hospitals had a combined bed capacity of 545,169, which has been augmented in the eleven years to 815,136. The average census in these facilities was 470,157 in 1927 and 736,687 in 1938. The very largely custodial nature of governmental hospitalization is, of course, well understood and particularly in relation to the state mental hospitals.

Over against this picture there is the record of the more active and more acute nongovernmental hospital, which now number 4,438 as compared with 4,998 eleven

years ago. The beds have mounted from 308,149 to 346,244 and the average census from 201,675 to 229,019. Striking as is the quantitative increase in hospital facilities for acute or active cases, there is also to be noted the increasing rapidity of turnover. Each year the average length of stay, particularly in general hospitals, is clipped shorter and shorter, now being twelve and one-half days.

available and in many cases are quite adequate for the community for which they are designed to serve.

Those nonprofit organizations which are designated as church hospitals numbered 1,060 at the beginning of the period and now show a total of 981. Their beds have increased from 108,582 to 119,521 and a corresponding increase is noted in patients cared for. It is common to refer to these as church hospitals largely

the first time in history this number has passed beyond the 1,000,000 mark. What percentage this is of all births for the year 1938 is not known because the final statistics for the year are not yet to be had. The latest available statistics give the total live births both inside and outside of hospitals for 1937 as 2,203,337.

The accompanying compilation of statistics on births in hospitals shows the figures for 1929, 1937 and 1938

Hospital departments of institutions	277	189	211
All other hospitals	1,561	401	392
<b>Total births in all hospitals</b>	<b>621,896</b>	<b>902,912</b>	<b>1,026,771</b>

thereby affording comparison between this year and last and also over a ten year period. In 1929 there were 621,896 births in hospitals and 83,541 of these, or 13.4 per cent, were in governmental hospitals, including all federal, state, county, city and city-county hospitals. Those same groups of governmental hospitals reported for 1938 a total of 178,534 births or 17.4 per cent of the births reported in all hospitals. The increase has been due mainly to extension of government aid

#### Hospitals, Sanatoriums and Related Institutions

	Hospitals	Beds	Bassinets	Births	Patients Average
Hospitals and sanatoriums	4,974	981,503	54,191	1,005,260	9,070,000
Related institutions	1,192	179,827	2,503	21,511	3,010,020
<b>Total registered hospitals</b>	<b>6,166</b>	<b>1,161,330</b>	<b>56,694</b>	<b>1,026,771</b>	<b>9,080,020</b>

to indigents and other beneficiaries. The large number of births in state hospitals comes mainly from the state university and charity hospitals used for teaching purposes. The county, city and city-county hospitals would, of course, participate in the general increased use of hospitals for maternity purposes, much the same as the nonprofit or other voluntary hospitals.

The Indian hospitals maintained by the Department of the Interior reported a total of 4,237 births.

While almost any size and type of a hospital or medical institution is at least occasionally used for childbirth, the largest share of this work by far goes to the general hospitals. In 1929 the general hospitals reported 566,177 births or 91 per cent of the total births for that year. In 1938 the general hospitals

reported 976,970 births, or 95.1 per cent of all the births for that year.

In 1929 there were 47,939 bassinets and the number of births was equivalent to thirteen per bassinet. In 1938 there were 56,747 bassinets and the births were equivalent to eighteen per bassinet.

#### SUPPLY AND UTILIZATION OF BEDS IN GENERAL HOSPITALS

In determining whether and where there is need of additional hospital facilities, it is obviously necessary first to ascertain the extent to which existing facilities are being utilized. In the accompanying table the states are arranged in the order of the number of their general hospital beds per thousand of population. Mississippi,

#### Supply and Utilization of Beds in General Hospitals

State	Beds per Thousand Population	Per Cent of Occupancy	Group Average

Colorado	5.3	64	
Arizona	5.6	58	
Montana	5.9	56	
Nevada	6.2	63	
District of Columbia	8.6	80	

Population estimated by the United States Bureau of Census July 1, 1937.

having the least hospital facilities, has 1.4 beds per thousand. At the other end of the scale, the District of Columbia has 8.6 beds per thousand, many of which, however, serve not the inhabitants of the District only but federal employees throughout the country.

Dividing the states into groups having hospital facilities in the ratio of 1 to 2, 2 to 3, 3 to 4, and so on, beds per thousand, the utilization of these facilities (per cent of occupancy) in each group steadily rises as the number of hospital beds increases. Four states with from

1 to 2 beds per thousand show a use of 59 per cent. The next group, twelve states, with hospital beds running from 2 to 3 per thousand, report 65 per cent occupancy. The next group, seventeen states with a ratio of from 3 to 4 beds per thousand, keep these beds 69 per cent filled. In ten states, with from 4 to 5 beds per thousand, utilization is 73 per cent. In four states having from 5 to 6 beds per thousand, occupancy drops to 60 per cent.

It is obvious, therefore, that hospital facilities are most used where they are most abundant and that where the ratio of beds to population is lowest the rate of occupancy is also lowest. In other words, hospitals have been built in response to a community demand and have not, as a rule, been built where there is no demand. Doubtless some states would show a higher rate of occupancy if additional funds were available for hospitalization of the indigent. In other states, education is needed to overcome popular prejudice. In any case, no single formula for hospital facilities is applicable to all parts of the country or to the habits and customs of all the people.

#### METHODS OF REGISTERING AND APPROVING HOSPITALS

The vast majority of hospitals in the Register have been in operation for a number of years and are therefore, more or less, permanent fixtures. Contact is maintained with them through the annual census and

(1934)	221	18 430	1 020
(1933)	210	18 794	1 036

through correspondence between the Council's office and the hospital field. Those registered hospitals which are approved for the training of interns and for residencies in specialties are subject to regular, thorough inspection by members of the Council's staff of hospital examiners. The inspected hospitals, therefore, receive more than one half of all the patients admitted to all hospitals each year. In addition to the approved hospitals the Council's examiners have visited more than a thousand other registered hospitals.

Other ways of knowing whether a hospital deserves continued registration include constant correspondence with officials of local and state medical societies and the cooperation of other agencies which are active in the evaluation of individual hospitals, including the American College of Surgeons, American Hospital Association, Catholic and Protestant hospital associations and various other national, regional and state organizations.

The Council must also have complete information regarding all prospective hospitals, projects, plans and prospects for new buildings, alterations and changes in capacity or status. Much of this information is obtained through the service of newspaper clipping bureaus and

through systematic checking of telephone directories, the news sections of hospital and medical journals, and lists of hospitals maintained by local and national governmental agencies. Most helpful are the hospitals themselves.

In the case of a new hospital or one that has changed ownership or status, the institution itself supplies information regarding its capacity, equipment, type of service and list of physicians, and in general it outlines the work which it is designed to do. When this information is received at the Council's office, the record of each physician is examined in the biographic files of the American Medical Association. Information and advice are obtained from officials of constituent and component medical societies where the hospital is located, also from state, city and county health departments. Inspections are made on request. A personal visit by a member of the Council's staff is sometimes made either through a special trip or when inspecting hospitals for intern and resident training in that district. When sufficient evidence has been obtained to justify a decision, the hospital's application and supporting data are laid before the Council in session.

These means of evaluating hospital service are employed as a matter of justice to the hospital and, above all, for protection to the public.

#### HOSPITALS REFUSED REGISTRATION

The 636 institutions refused registration are not included in our compilation of statistics. Their capacity equals a little more than 1 per cent of that of the registered hospitals. From the standpoint of hospitalization, therefore, they are not needed.

These concerns, because of alleged unethical or questionable practices, admission to their staffs of members who are seriously unqualified either morally or professionally, flagrant methods of advertising or for other valid reasons, are deemed unworthy of being included in any published list of reputable hospitals. Not only are they left out of the Register and the American Medical Directory but their names are consistently omitted from all publications of the Association and they are refused admission to the advertising columns.

The public is thus helped to distinguish between the good and the bad in hospitals. As a result, it is considered a disgrace among hospitals and physicians to be refused registration, and institutions that are rejected are frequently aroused and correct the objectionable practices in order that they may be recognized. Public and professional opinion forces many such institutions to sell their buildings to more reputable owners or to close up.

The Register is used as a basic list of hospitals. Industrial and governmental agencies use it in selecting hospitalization for their dependents and beneficiaries. Physicians consult it when referring patients.

Other organizations have shared largely in the good work that the American Medical Association has accomplished by its vigilance in distinguishing between the fit and the unfit in the hospital field. The American College of Surgeons has cooperated by refusing to consider for its approval an unregistered hospital, and the American Hospital Association has followed the Register in considering applications for institutional membership. It is evident also that the public in general limits its patronage and its donations to hospitals that are considered worthy of a place in the Register.

Opportunity is always open to unregistered hospitals to mend their ways and merit registration.

## INTERNSHIPS, RESIDENCIES AND FELLOWSHIPS

## NUMBER OF INTERNSHIPS

At present 734 hospitals are approved for the training of interns. These provide a total of 7,373 internships, but only about 6,100 positions are available each year. A comparison with the number of graduates in the United States, 5,194 in 1938, indicates that approximately 900 positions cannot be filled from our own medical schools.

Obviously this does not represent the actual number of vacancies, for many positions are held by second year

TABLE A—Growth of Internships

	Number of Hospitals	Available Internships	Medical Graduates (U S)
1914	603	3 095	3 594
1920	510	3 119	3 120
1930	614	5 531	4 567
1934	712	7,167	5 377
1938	729	7 373	5 194

interns, foreign graduates and applicants from Canadian medical schools. (Total graduates, United States and Canada, 5,691.)

The fact remains, however, that currently a relative shortage of interns exists and many hospitals are finding it difficult to complete their house staffs. An institution faced with this problem should attempt to employ second year interns either on a rotating basis or in the capacity of general residents. Should the difficulty persist the hospital might find it advantageous to transfer its entire educational service to a general residency plan.

## TYPES OF INTERNSHIPS

The Council on Medical Education and Hospitals approves rotating and mixed internships and straight intern services in medicine, surgery, pediatrics and pathology. Of the approved intern hospitals 622 offer a full rotating service with assignments in medicine, surgery, pediatrics, obstetrics and the laboratories. Sixty-nine have mixed internships which represent more than one of the clinical specialties but do not include all of the divisions listed above. Fifteen hospitals offer straight internships limited to a single specialty, while twenty-three have straight services in addition to the rotating or mixed types.

At present there are twenty-seven hospitals offering straight internships in medicine, twenty-six in surgery, thirteen in pediatrics and fifteen in pathology. A few are providing straight internships in the limited fields of cardiology, dermatology and syphilology, obstetrics, ophthalmology-otolaryngology, neurology, psychiatry, neurosurgery, radiology and urology. It is now generally agreed that training in limited specialties should be reserved for residents, fellows or other graduate students who have already fulfilled the educational requirements of the intern year.

## LENGTH OF INTERNSHIPS

By reference to table B and the corresponding tabulation in the Hospital Number of the THE JOURNAL March 26, 1938, it will be noted that there has been little change in the length of internships. Most of the services are still on a one year basis, although an appreciable number extend over a period of eighteen months or two years. A total of 578 hospitals have internships of one year's duration, while twenty-six are of eighteen months and eighty-four of two years or more.

## MINIMUM NUMBER OF INTERNS

In estimating the quality of intern training, one of the factors to be considered is the case load in relation to the size of the house staff. While it is difficult to state the optimum relationship that should exist, it has been determined by actual study of educational services that the average ratio in some of the leading hospitals is approximately one intern to 450 or 500 admissions a year.

Since hospitals approved for intern training are required to maintain an annual admission rate of 2,000 patients or more, it is apparent that any institution offering an educational program in accordance with the Essentials of the Council should employ at least three and preferably four interns. It has frequently been noted that single internships and services employing only two men are poorly organized and far too often present an indiscriminate assignment of duties based largely on institutional rather than educational needs. Usually there is an unbalanced service with interns being required to devote an excessive amount of time to surgery, emergencies and ordinary routine procedures.

Hospitals that are not in position to offer an organized training program for at least three interns should not assume the educational responsibilities of the fifth year of medicine. Their type of service is better suited to the continued training of second year men who wish to secure additional hospital experience of a general nature.

At present there are forty hospitals which employ less than three interns. Nearly twenty have a capacity in excess of 150 beds and admit more than 3,000 patients a year. These institutions should consider the

TABLE B—Number and Length of Internships According to Type

Type	12 Months	14 Months	15 Months	16 Months	18 Months	21 Months	22 Months	Over 21 Months	Variable	Total	Number of Interns

Combination	7						1		10	23	137
	578	1	2	1	26	1	81	3	30	720	6,351

advisability of transferring their educational service to a general or mixed residency basis as recommended above.

## CANCELLATION OF CONTRACTS

Since July 1, 1938, the Council has received notification of 138 internships and residencies terminated without fulfillment of contracts. Reports received from hospitals and individuals concerned indicate that 114 appointments were discontinued by mutual consent, seventeen were vacated without the approval of the hospital and seven ended in dismissal for infraction of the rules. As far as can be determined, the cancellations resulted from the following causes:

More desirable appointment available	44
To enter private practice	21
General dissatisfaction	20
Illness	11
Financial difficulties	11
Failure to complete medical course	10
Dismissal for infraction of rules	7
Various personal reasons	7
Illness at home	4
Failure of hospital to verify appointment	3

The Council expects both the hospital and the appointee to observe the terms of the residency or internship agreement. This should preferably be in the form of a written contract best to protect the interest of both parties. On the part of the hospital

there is an obligation to furnish instruction and clinical training in accordance with the essentials governing intern or residency training. Consequently if conspicuous defects exist in the quality of the educational service the position of the hospital is immediately impaired. On the other hand, it is expected that interns and residents conform to the traditions of the profession, that they conduct themselves in an ethical manner and that their action be such as to protect the welfare of patients and the interests of the hospital if circumstances should develop that would necessitate readjustment of contracts. Hospitals have always been generous in granting leave of absence or permitting the appointee to withdraw from active service when requests are based on justifiable grounds. It is expected that interns and residents be equally considerate of the hospital needs and that ample time be given to permit the management and staff to rearrange the services or employ a satisfactory substitute. Failure to fulfil a contract in the absence of a satisfactory explanation will be recorded in the biographic files of the American Medical Association. Notice of such action is sent to the intern's medical school and may be furnished on request to hospitals where new appointments are sought and to licensing and certifying boards. Termination of contracts without consent is viewed with such seriousness

that the Washington State Medical Association has recently passed a resolution requiring applicants for county medical society membership to submit evidence that internship contracts have been satisfactorily fulfilled. Further reference to incompleting internships is contained in the A M A Interns' Manual, pages 16 and 17.

#### GRADUATES OF FOREIGN MEDICAL SCHOOLS

The influx of graduates from foreign medical schools is continuing as a problem of major importance from the point of view of hospital training, licensure and subsequent adjustment in the field of medical practice. During the academic year 1937-1938 there were 1,346 citizens of the United States enrolled in faculties of medicine abroad and 318 completed the medical course. This is only part of the problem, however, since in 1937 there were 919 foreign graduates admitted to the licensing examinations in various states and 147 licensed by endorsement of credentials.

Many of the foreign graduates are seeking appointments as interns in approved hospitals. In 1937, for

example, there were 245 employed in 105 hospitals throughout nineteen states. Last year 149 approved hospitals in twenty-nine states reported a total of 312. Reference to table C will show that hospitals in Eastern states are absorbing most of the foreign graduates, especially New York, New Jersey, Pennsylvania and Connecticut. A considerable number are also employed in hospitals in Ohio and Illinois.

The American Medical Association has adopted the following resolution in an effort to solve the perplexing problems associated with graduates of foreign medical schools

*Resolved*, That when suitable graduates of class A schools of the United States and Canada are not available, hospitals

TABLE C—Hospitals Employing Foreign Graduates

Furthermore, it devolves on individual hospitals to determine the identity of the candidate, the authenticity of his credentials, and that his professional qualifications are acceptable. Most hospitals are quite unpre-

pared to verify and evaluate foreign credentials, since faculties of medicine abroad have not been inspected and classified as in the case of American and Canadian schools. Applicants should therefore be required to submit translations of medical diplomas and licenses to practice over the signature of the nearest consul representing the country in which the training was obtained. The professional qualifications can be determined by the candidate's ability to pass parts I and II of the National Board. As a matter of fact this serves also as a convenient method of verifying foreign credentials.

In anticipation of taking the foregoing examinations, foreign graduates may be accepted in the capacity of substitutes, but their continued employment should be contingent on the successful passing of parts I and II of the National Board. In other words a permanent appointment should not be made until these requirements have been fulfilled, nor should the internship begin until official notification is received from the National Board that parts I and II have been success-

TABLE E—Approved Internship Hospitals with Highest Necropsy Percentages (Includes All Over 70 per Cent Reported for 1938)

	Control	Necropsy Percentage
1 Trinity Hospital Minot N D	Church	86.4
2 Mary Hitchcock Memorial Hosp Hanover N H	NPAssn	84.6
3 University of Nebraska Hospital Omaha	State	84.2
4 U S Naval Hospital Washington D C	Navy	83.3
5 Ancker Hospital St Paul	City Co	81.7
6 University Hospitals Minneapolis	State	81.3
7 Kansas City General Hospital Kansas City Mo	City	81.2
8 University of Chicago Clinics Chicago	NPAssn	80.8
9 U S Marine Hospital Norfolk Va	USPHS	79.2
10 University of Kansas Hospitals Kansas City Kan	State	78.9
11 Colorado General Hospital Denver	State	76.6
12 Johns Hopkins Hospital Baltimore	NPAssn	76.0
13 St Luke's Hospital Kansas City Mo	Church	75.8
14 Montefiore Hosp for Chronic Diseases New York	NPAssn	75.1
15 University of California Hospital San Francisco	State	74.8
16 St Francis Hosp and Sanit Colorado Springs	Church	74.0
17 Iowa Methodist Hospital Des Moines	Church	73.7
18 Hospital of the Protestant Episcopal Church Philadelphia	Church	70.1
19 Albany Hospital Albany N Y	NPAssn	74.0
20 U S Marine Hospital Baltimore	USPHS	72.0

22 Beverly Hospital Beverly Mass	NPAssn	70.8
23 Presbyterian Hospital Philadelphia	Church	70.8
24 St Joseph Hospital Kansas City Mo	Church	70.1

fully completed. Needless to say a certificate of internship should not be granted until these provisions have been fulfilled.

#### COMPUTATION OF NECROPSY PERCENTAGE

In the computation of necropsy rates in hospitals approved for intern training, all deaths are considered with the exception of still-births. No attempt is made to differentiate between institutional and noninstitutional deaths as based on a twenty-four or forty-eight hour classification, but due allowance is made in accordance with the following resolution of the Council when legal restrictions interfere with the use of pathologic material for teaching purposes.

*Resolved*, That those cases removed from the jurisdiction of a hospital by coroner or medical examiner, and in consequence not available as teaching material for interns, may be deducted from the total hospital deaths in computing autopsy percentages. This provision also extends to bodies legally assigned to qualified educational institutions for dissection.

From this it is apparent that coroner's cases may be excluded from the compilations if the hospital is prevented by regulation from conducting its own examinations. In other words, no penalty attaches to the hospital when bodies are removed from the institution through legal methods and over which the hospital has

no control On the other hand, coroner's cases may be included in the compilation if they serve a genuine educational purpose, that is, they are performed on the premises of the hospital by a qualified pathologist, they may be witnessed by members of the house staff and a complete protocol exists in the hospital record system

TABLE F—Number and Length of Residencies According to Specialties—1938

Specialty	Number of Hospitals							Number of Residencies
	12 Months	16 to 21 Mos	24 Months	25 to 34 Mos	36 Months	Over 36 Mos	No Report	
1 Internal Medicine

g Anesthesia	12		3		4		19	62
7 Orthopedic surgery	34	3	7	1	12	1	58	130
8 Urology	33		8	2	6	3	53	88
9 Ophthalmology	19	6	7	1	7	2	42	120
10 Otolaryngology	26	2	10	1	5	2	51	193
11 Pathology	80		17		13	2	118	188
12 Radiology	39	1	14		19		73	129
Physical therapy	2						2	2
	808	31	179	11	208	47	719	3,499

The following report is employed as an illustration of the present method of computing necropsy percentages

Number of stillbirths	12	Necropsies	5
Coroner's cases	29	Necropsies	16
All other deaths	190	Necropsies	72
Coroner's necropsies performed by hospital pathologist			7

By allowing full credit for seven coroner's cases, a rate of 40.1 per cent is obtained on the basis of  $(72 + 7) - (190 + 7)$

It is permissible, of course, that hospitals exclude from their necropsy statistics the deaths which occur in the ambulance or in the emergency room before admission to the hospital service has actually taken place. Logically it follows that necropsies on deaths occurring outside the institution should not be included in the calculation of hospital rates. Even though official credit is not assigned for postmortem studies of this type, it is nevertheless desirable that outside material be utilized whenever available. Attention is called to tables D and E, showing the highest necropsy rates for 1937 and 1938.

#### REVISION OF NECROPSY REQUIREMENTS

It has long been apparent that necropsy percentage alone is not a satisfactory index of the amount of pathologic material available for house staff instruction

Accordingly the Council has added the requirement of thirty-six necropsies a year, effective in 1940 in hospitals approved for intern training. The minimum rate of 15 per cent will likewise continue in force.

Under ordinary circumstances it would seem that one postmortem examination a week is essential for teaching purposes especially if clinical-pathologic conferences and other educational activities are carried out in accordance with present essentials. Therefore, a minimum of thirty-six necropsies a year cannot be considered an excessive requirement. Admittedly the hospitals which have less than 100 deaths may find it difficult to obtain a rate above 36 per cent, but the problem should not be considered insurmountable since already the average necropsy rate in hospitals for intern training has reached a level of 34.4 per cent.

At present the hospitals with less than thirty-six necropsies offer only 517 internships in a total of 7,354. The majority of these institutions have more than twenty-five postmortem examinations a year and should experience little difficulty in increasing the number to a satisfactory level.

#### Pathology Departments

State	Hospitals Having Clinical Laboratories		M D Directors	
	1937	1938	1937	1938
Alabama	63	66	41	47

Washington	79	77	60	65
West Virginia	67	68	01	48
Wisconsin	135	145	96	101
Wyoming	18	18	13	13
Totals	4,027	4,673	3,002	3,601

Regardless of the emphasis on quantitative measures, it is understood, of course, that quality of necropsy service is still of paramount importance. Quality is based chiefly on the competence of the hospital pathologist, completeness of anatomic and histologic studies, adequacy of reports, the extent to which pathologic material is utilized for teaching purposes and the degree to which interns and staff members participate in these activities.

## RESIDENCIES AND FELLOWSHIPS

The Council has recently extended the residency classification to include fellowships and henceforth the list of hospitals approved for residencies in specialties will be published under the title of "Approved Residencies and Fellowships." In extending the scope of the residency field it became necessary to formulate new definitions and standards of graduate training as described in the Essentials of Approved Residencies and Fellowships. The new Essentials set forth the general standards applicable to all types of residency and fellowship training and also the specific requirements pertaining to individual specialties. They are purposely of a detailed and comprehensive nature so as to aid in the organization of residency programs especially in institutions that are not familiar with the methods of graduate training.

Residencies and fellowships in the clinical branches of medicine and surgery, pathology and radiology represent advanced training usually in preparation for the practice of a specialty. Residencies in specialties, as defined by the Council, are straight services of one or more years following an approved internship. A fellowship is a form of apprenticeship which in some cases is indistinguishable from a residency although it usually offers greater opportunity for the study of basic sciences and research. Ordinarily a fellowship is a university rather than a hospital appointment. Mixed residencies are general hospital assignments following internship. (They include services classified as general residencies and chief residencies.) In all instances the term of service should be at least twelve months and might well be extended to two or more years when suitable facilities are available.

Approved residencies and fellowships are offered in the following branches of medicine:

- |                               |                                 |
|-------------------------------|---------------------------------|
| 1 Anesthesiology              | 16 Ophthalmology                |
| 2 Cardiology                  | 17 Ophthalmology otolaryngology |
| 3 Communicable diseases       | 18 Orthopedic surgery           |
| 4 Dermatology and syphilology | 19 Otolaryngology               |
| 5 Epilepsy                    | 20 Pathology                    |
| 6 Fractures                   | 21 Pediatrics                   |
| 7 Gynecology                  | 22 Physical therapy             |
| 8 Malignant diseases          | 23 Plastic surgery              |
| 9 Medicine                    | 24 Psychiatry                   |
| 10 Mental deficiencies        | 25 Radiology                    |
| 11 Mixed residency            | 26 Surgery                      |
| 12 Neurology                  | 27 Thoracic surgery             |
| 13 Neurosurgery               | 28 Traumatic surgery            |
| 14 Obstetrics                 | 29 Tuberculosis                 |
| 15 Obstetrics gynecology      | 30 Urology                      |

There is currently a widespread interest in educational activities designed to meet the requirements of the specialty boards. Thus there are constantly increasing demands for specialized training in institutions approved by the Council. As new residencies and fellowships are developed there is usually an immediate request for approval in order that credit may be registered in the files of the American Medical Association. The procedure involved in the evaluation and certification of residencies in specialties has previously been described in the Hospital Number of THE JOURNAL, March 26, 1938, page 978.

On Sept 1, 1938, there were 451 approved hospitals offering training to 3,499 residents and assistant residents. Recent approvals, including the fellowships of the Mayo Foundation, have increased the number of institutions to 503 and individual residencies and fellowships to 3,977. Reference should be made to table F, showing the number and length of residencies according to specialties.

SCHOOLS FOR OCCUPATIONAL  
THERAPY TECHNICIANS

The "Essentials of an Acceptable School of Occupational Therapy" were adopted by the American Medical Association at the Atlantic City session in June 1935. The inspection of occupational therapy schools and the formulation of standards were made following a resolution designed for these purposes and presented to the House of Delegates of the American Medical Association by Dr J Gurney Taylor of Wisconsin at the Milwaukee session in June 1933.

The Board of Trustees recommended that the Council on Medical Education and Hospitals undertake the survey promulgate standards and maintain a list of acceptable schools. The Council on Physical Therapy of the American Medical Association and the American Occupational Therapy Association lent their full cooperation and advice in the study and preparation of standards. The "Essentials of an Acceptable School of Occupational Therapy" were published in THE JOURNAL, May 4, 1935, Aug 31, 1935, and Aug 29, 1936. Changes relating to subjects and hours and a clause permitting the concentration of technical training in one field were proposed and approved by the Council on Feb 12, 1938. The revised "Essentials" were published in THE JOURNAL, March 26, 1938.

The following schools substantially conform to the minimum requirements adopted by the American Medical Association and approved by the Council on Medical Education and Hospitals.

APPROVED SCHOOLS OF OCCUPATIONAL  
THERAPY

**Boston School of Occupational Therapy** Boston—Organized in 1918 as a war time measure. Incorporated in 1921 as a nonprofit institution. Control is under a board of thirty-four trustees. The faculty is composed of thirty-seven regular members, forty-three lecturers and fourteen extramural instructors, ninety-four in all. The educational requirement is one year of college or equivalent. The duration of the course is three academic years. A total of sixteen hospitals and other institutions is used in practice training. The tuition fee is \$300 a year. Thirty students are admitted annually. The next session begins in September 1939. The director is Mrs John A Greene.

**Kalamazoo State Hospital School of Occupational Therapy** Kalamazoo, Mich.—Organized in 1922. Governed by a joint committee of Kalamazoo State Hospital and Western State Teachers College, Kalamazoo. Affiliated with Western State Teachers College in 1936. The faculty includes twenty instructors in the hospital and six in the college, six lecturers and five extramural instructors, a total of thirty-seven. Two courses are offered: the diploma course of twenty-seven months requiring graduation one year of college and a five year course requiring graduation from an accredited high school and leading to a BS degree from Western State Teachers College. The school is affiliated for practice training with five hospitals and other institutions. No tuition is charged for the diploma course; miscellaneous expenses are about \$270. The student pays the regular college fee for courses at Western State Teachers College. Twelve students are admitted each year. The next class begins August 1939. The director is Miss Marion R Spear, BS OT Reg.

**St Louis School of Occupational and Recreational Therapy** St Louis.—Organized in 1918 as a war time measure. Conducted by the Missouri Association for Occupational Therapy and governed by a board of trustees. Affiliated with Washington University School of Medicine and University College. The faculty includes thirty regular instructors, twenty lecturers and twelve extramural instructors, a total of sixty-two. Two courses are offered: the diploma course of three academic years (twenty-seven months) requiring for admission two years of college work or equivalent and a five year course (forty-five months) requiring graduation from an accredited high school and leading to a BS degree from Washington University. Practice training is given in a total of thirteen affiliated hospitals and other institutions. The annual tuition fee for the diploma course is \$320 and for the degree course \$280. Fifteen students are admitted each year. The next session begins in September 1939. The director is Miss Geraldine R Lermitt, AB Ph M OT Reg.

**Philadelphia School of Occupational Therapy** Philadelphia—Organized in 1918. Incorporated in 1923 as a nonprofit organization. Management is vested in a board of directors. An affiliation exists with the University of Pennsylvania. The faculty includes nine instructors in therapeutic occupations, twenty-six in theoretical subjects and seventeen extramural instructors, a total of fifty-two. The entrance requirement is one year

of college or equivalent The course covers three academic years or twenty-eight months Practice training is given in a total of eighteen affiliated hospitals and other institutions including the Graduate Hospital of the University of Pennsylvania The tuition fee is \$650 Approximately forty students are admitted each year The next session begins in September 1939 The director is Miss Helen S Willard B A O T Reg

**Milwaukee Downer College Department of Occupational Therapy**  
Milwaukee—Course in occupational therapy organized in 1913 Management of the college is vested in a board of thirty-two trustees The department's faculty includes fourteen instructors in the college eight lecturers and eight extramural instructors thirty in all Two courses are offered the diploma course of three academic years requiring for admission one year of college or equivalent and a five year course requiring graduation from an accredited high school and leading to a B S degree Practice training is given in nine affiliated hospitals and other institutions The annual tuition fee for the diploma course is \$250 and for the degree course \$230 Approximately fifteen students are admitted each year The next session begins in September 1939 Miss Marjorie Taylor O T Reg is director of occupational therapy

**University of Toronto Department of University Extension Toronto Ont Canada**—Course in occupational therapy organized in 1926 The regular occupational therapy faculty numbers twenty-seven including instructors lecturers and demonstrators and in addition there are nine extramural instructors a total of thirty-six The admission requirement is one year of college The duration of the course is three academic years or twenty-four months Hospitals and other institutions affiliated for practice training number eleven The annual tuition fee is \$150 Twenty-five students are admitted each year The next session begins in September 1939 The supervisor of the course is Miss Helen P LeVesconte

## ESSENTIALS OF AN ACCEPTABLE SCHOOL FOR PHYSICAL THERAPY TECHNICIANS

### I ORGANIZATION

1 Acceptable schools for training physical therapy technicians may be conducted by accredited universities colleges or hospitals

2 The Council has promulgated standards for this type of training to supply physicians hospitals and prospective students with reliable information and for the protection of the public

3 Responsibility for courses in hospitals should be placed on the hospital administration rather than the director of the department In colleges and universities this responsibility is on the controlling board, as for other courses

4 Resources for continued operation of the school should be insured through regular budgets, gifts or endowments but not entirely through students tuition fees Experience has shown that commercial schools operated for profit frequently do not adhere to proper ethical and educational standards and are not acceptable

5 There must be available transcripts of high school, college work and other credentials Attendance and grades of students shall be carefully recorded, by means of which an exact knowledge may be obtained regarding each student's work

6 At least two or more students should be enrolled in each class

### II FACULTY

7 The school should have a competent teaching staff Appointments should be based on thorough education and training and successful teaching experience The staff should include not less than one qualified salaried instructor and in each institution where practical training is carried on not less than one qualified physical therapist The question of full time and part time appointments is not as important as the qualifications of the instructors who should be specialists or exceptionally well trained and well qualified in the lines they are teaching

### III FACILITIES

8 Provision should be made for each student to receive practice training adequate in kind and amount under the supervision of a physician qualified in physical therapy in a hospital or other institution acceptable to the Council on Medical Education and Hospitals of the American Medical Association

9 Adequate equipment should include anatomic charts models and other aids to effective teaching It is suggested that dissecting materials should be provided to enable each student

to dissect or have the benefit of demonstration of dissection of at least the lateral half of the human cadaver Skeletons and disarticulated bones should be supplied

10 A library containing up-to-date references, texts and scientific periodicals pertaining to physical therapy should be maintained

### IV ADMINISTRATION

11 There should be careful and intelligent supervision of the entire school by an executive officer who, by training and experience is fitted to interpret the prevailing standards in physical therapy education and who is clothed with sufficient authority to carry them into effect

12 Except for good cause, such as for illness no credit should be given for any course when the attendance has been less than 90 per cent of the full time

### V REQUIREMENTS FOR ADMISSION

13 Candidates for admission should be able to satisfy one of the following requirements

- (a) Two years or sixty semester hours of college, including courses in physics and biology
- (b) Graduation from an accredited school of nursing
- (c) Graduation from an accredited school of physical education

Courses in general physics, chemistry and biology are highly recommended for all who seek to enter training in physical therapy

14 The admission of students to the physical therapy school must be in the hands of a responsible committee or examiner whose records shall always be open for inspection Documentary evidence of the student's preliminary education should be obtained and kept on file When the physical therapy school is an integral part of the university, this work usually devolves on the university examiner

15 Advanced standing may be granted to students for work done in other acceptable physical therapy schools or hospital departments, provided the entrance requirements and other essentials herein set forth have been complied with Official verification of the student's previous physical therapy work should be obtained by direct correspondence with the schools previously attended, and his preliminary qualifications should also be verified and recorded the same as for first-year students

16 Complete physical examination of each student admitted should be conducted under the auspices of the school

### VI PUBLICATIONS

17 The school should issue at least annually, a bulletin setting forth the character of the work which it offers Such announcement should contain a list of the members of the faculty with their respective qualifications

### VII MINIMUM CURRICULUM

Subjects	Hours	
	Theory	Laboratory and Practice Training
Anatomy (including applied anatomy demonstration on cadaver and lecture)	210	
Clinical practice		400
Electrotherapy	30	45
Ethics and administration	5	
Hydrotherapy	5	15
Massage	15	45
Pathology	30	
Physiology	30	45
Principles of physical therapy as applied to		
Medicine	15	30
Neurology	10	15
Orthopedics	15	30
Surgery (including surgical observation)	15	30
Psychology	15	
Therapeutic exercise	30	75
Electives	45	
Total	470	730
		1 200 hours

Suggested electives asepsis, bandaging, first aid history of physical therapy hygiene joint measurements office routine, occupational therapy records social service

All subjects should be taught by qualified teachers

Length of course Not less than nine months

### SCHOOLS FOR PHYSICAL THERAPY TECHNICIANS

The survey of schools for physical therapy technicians was assigned to the Council on Medical Education and Hospitals in 1934. Following the initial inspection and study of thirty-five schools the "Essentials" were formulated and adopted by the Council and passed by the House of Delegates of the American Medical Association.

tion on May 9, 1936. The first list of approved schools appeared in THE JOURNAL Aug. 29, 1936, and several lists have been published since.

At the November 1937 meeting of the Council, certain changes were made in the "Essentials" for the purpose of clarification of meaning but which did not alter the original considerations in the requirements. The Council on Physical Therapy of the American Medical Association, the American Congress of Physical Therapy and the American Physiotherapy Association lent their full cooperation in the preparation of the original standards and continue to aid the Council in the consideration of new schools and in problems dealing with the "Essentials."

No standards for graduate courses for technicians have as yet been promulgated. The Mayo Clinic now offers organized graduate courses for technicians.

The "Essentials of an Acceptable School for Physical Therapy Technicians" aim to provide more adequate facilities for the training of technicians. The investigations of the various courses during the past few years have revealed in many cases a deplorable lack of requirements, organization, qualified faculty and par-

ticularly clinical material with which students can develop skill in the application of this knowledge. These conditions exist principally in so-called commercial schools. Approval is withheld by the Council for courses where arrangements are such that students are enrolled without the necessary preliminary background and proceed across a well paved short cut in their efforts to enter this highly technical field.

Advertising commercial schools which adhere to no particular standards are turning out each year large numbers of inadequately prepared technicians. Nevertheless recent attention has been drawn to the fact that there is an acute shortage of graduates of approved schools.

The American Registry of Physical Therapy Technicians sponsored by the American Congress of Physical Therapy has now become recognized as a reliable means of identifying those qualified. The Board of Registry accepts for examination graduates of schools approved by the Council on Medical Education and Hospitals. Information concerning registration may be secured

\* Including schools approved and those unapproved by state board of nurse examiners as of January 1939. On this date there were 1,230 approved schools.

from Miss Marion G. Smith, registrar of the American Registry of Physical Therapy Technicians, 30 North Michigan Avenue, Chicago.

It is the desire of the Council on Medical Education and Hospitals to cooperate in every way with any hospital or educational institution in an effort to develop more well organized and well administered courses for technicians in the United States.

University of Wisconsin, Madison <sup>15</sup>	E A Pohle, M D	(a) R N (b) Grad phys ed	9-12 mos	<sup>a</sup>	20	Univ fees	Certificate

#### AFFILIATED CLINICAL FACILITIES

- Glendale Sanitarium and Hospital, Glendale and Los Angeles
- Cedars of Lebanon Hospital, Los Angeles County Hospital and Presbyterian Hospital—Olmsted Memorial, Los Angeles and others
- Langdon School for Crippled Children, Washington, D C
- Michael Reese Hospital, Passavant Memorial Hospital and St. Luke's Hospital, Chicago and others
- Boston City Hospital, Children's Hospital, Massachusetts General Hospital and Robert Breck Brigham Hospital, Boston and others
- Children's Hospital, Harvard Infantile Paralysis Commission, Clinic Industrial School for Crippled and Deformed Children and Massachusetts General Hospital, Boston and others
- Massachusetts General Hospital, Massachusetts Memorial Hospital and Perkins Institute for the Blind, Boston and Cambridge Hospital, Cambridge and others
- Blind Sanatorium and Hospital, Arlington Heights and Beth Israel Hospital and Industrial School for Crippled and Deformed Children, Boston and others

- Colonial Hospital, Kahler Hospital, St. Mary's Hospital, and Worrall Hospital, Rochester
- Firmen Desloge Hospital, St. Louis
- Buffalo City Hospital, Buffalo
- French Hospital and New York Hospital, New York City
- Allegheny General Hospital, Children's Hospital, Falk Clinic and St. Francis Hospital, Pittsburgh and others
- University of Virginia Hospital, Charlottesville and Crippled Children's Hospital, Stuart Circle Hospital, and Wheelon Clinic, Richmond and others
- State of Wisconsin General Hospital and Wisconsin Orthopedic Hospital for Children, Madison

#### NOTES

- Four year course leads to B S degree from Simmons College
- Four year course leads to B S degree from State Teachers College, Hyannis
- Twelve months course for those with three years of college
- Preferably in summer semester

### SCHOOLS FOR CLINICAL LABORATORY TECHNICIANS

The American Medical Association through its Council on Medical Education and Hospitals adopted requirements for acceptable schools for clinical laboratory technicians in 1936. The report of the original survey of some 200 courses was published in *THE JOURNAL*, Aug 29, 1936.

The American Society of Clinical Pathologists, which maintains the Registry of Medical Technologists, cooperates with the Council in the promulgation of standards for schools, in the consideration of new applications and in the maintenance of the approved lists. The registry has requirements similar to those of the American Medical Association and admits to its examinations the graduates of approved schools. In agreement with the Board of Registry the Council voted in 1937 to increase the admission requirement from one to two years of college work including basic sciences. This ruling became effective in 1938.

Commercial advertising schools are not considered eligible for recognition under the "Essentials of an Acceptable School for Clinical Laboratory Technicians," viz "Acceptable schools for training laboratory technicians may be conducted by universities, colleges, hospitals or public health laboratories." Training in commercial schools alone is not sufficient to permit students to enter the examinations of the Board of Registry.

The Council continues to inspect schools applying for recognition as well as those already approved. Questionnaires giving up-to-date general information concerning courses are requested annually from each school. The list of approved schools is revised each year and published in *THE JOURNAL*.

The "Essentials of an Acceptable School for Clinical Laboratory Technicians" may be obtained by writing to the Council on Medical Education and Hospitals. Information concerning the Registry of Medical Technologists is available through the registrar, Mrs. Anna R. Scott, 234 Metropolitan Building, Denver.

## NOTES

- Nurses are required to have one year of college
- For Negro students only
- Course includes training in x ray
- A one year course leading to an M S degree is also offered
- A B S degree is required for admission
- A four year course leading to a B S degree is also offered
- Students from other than affiliated colleges must have B S degree
- From Wayne University Detroit or Michigan State College, Lansing
- Students from other than affiliated colleges must have degree
- Students from other than affiliated university must have degree
- Covers lunches laundry breakage and material
- Unives are supplied
- 1 Late summer or fall
- Covers breakage, fee and materials used
- Credit may be applied toward B S degree following three years at College of William and Mary

- City Board of Health and Laboratory Albion
- Whitford Laboratories Beaumont
- Whitford Laboratories Beaumont
- Holbert F and F. L. for code 17 at Boston

The following list contains the names of 6,166 hospitals, sanatoriums and related institutions that are located in the United States and 259 in Alaska, Canal Zone, Guam, Hawaii, Philippine Islands, Puerto Rico and Virgin Islands. It omits the names of 636 hospitals which, after investigation, were not accepted. Registration of hospitals is governed by the Essentials of a Registered Hospital, adopted by the House of Delegates in 1928. Methods of registering and approving hospitals are given on a previous page. The inclusion of the name of any institution may be taken as an indication that evidence concerning irregular or unsafe practices in that institution has not come to the attention of the Council on Medical Education and Hospitals. The list in each state is given in two sections: (1) hospitals and sanatoriums, and (2) related institutions. The related institutions include some general hospitals lacking certain essentials: nursing homes, school infirmaries, prison infirmaries, custodial and other institutions designed to give some medical, nursing or convalescent care in an ethical and acceptable manner, but not strictly hospitals. In the statistics the two classifications are consolidated.

- \* Approved for general internship the fifth year in medicine by the Council on Medical Education and Hospitals
- + Approved for certain residencies in specialties for graduates in medicine who have already had a general internship or its equivalent in private practice

## APPRECIATION FOR COOPERATION

The vast amount of accurate data presented in this issue of THE JOURNAL relative to the hospitals of the United States and the educational aspects of hospital care is made possible by the personal cooperation of great numbers of administrators of hospitals and of other workers in this field. When it is realized that all this material has been accumulated, tabulated and presented within less than three months after the close of the year covered, the promptness of the response becomes apparent. The Council on Medical Education and Hospitals and THE JOURNAL wish to express thanks and appreciation to all of those who have given cooperation, for without their help such presentation would not have been possible. It is hoped also that the cooperation may be taken as a recognition of the confidence which hospital administrators and workers in the field of medicine have in the work of the Council. This confidence is highly prized.

## HOSPITAL SERVICE 1938

The list published in this issue of THE JOURNAL indicates 6,166 registered hospitals. A year ago there were 6,128. For the first time since 1930 the number has increased over the previous year. Other evidences also point to more than ordinary expansion in hospital facilities but at the same time a greater number of idle beds.

The number of beds in registered hospitals is greater than a year ago by 36,832, about 50 per cent more than the average annual gain. There is an increase of 1,181 bassinets.

Since 1909 hospital facilities have increased each year by an average of 24,677 beds, or the equivalent of a sixty-eight bed hospital for every day in the year, Sundays and holidays included. During 1938 the net gain in registered hospital facilities was equal to a 101 bed hospital for each day of the year. Sixty-seven hospitals are known to be under construction and 185 additional ones are planned with construction pending.

Supplementary to these facilities there are 2,529 institutions, emergency stations, clinics and cottages designed to give emergency and other auxiliary types of hospital and medical care of which the Council on Medical Education and Hospitals has record.

The extent to which the people have absorbed expanding hospital facilities is attested by the admission of 9,421,075 patients to all registered hospitals, the equivalent of one person in every fourteen of the entire population. The registered hospitals admitted patients at the rate of one every three and three-tenths seconds throughout the entire year, day and night, Sundays and holidays included. The average stay per patient in general hospitals was 12.5 days. More than a million babies, 1,026,771 to be exact, were born in hospitals during the year.

The growth of hospital facilities has outstripped the advance in population. The increase of population in the United States from July 1, 1927, to July 1, 1938, was 8.9 per cent. In the same time the beds in all registered hospitals increased 36.1 per cent. The beds in all general hospitals increased 23.2 per cent, in nervous and mental hospitals 58.5 per cent and in tuberculosis hospitals 20.3 per cent. The ratio of general hospital beds to population has increased during these years from 2.9 beds per thousand to 3.3 beds per thousand. Such increases in proportion to population cannot be maintained indefinitely.

Hospital facilities must be provided where and when needed. They must be the implements of competent medical, nursing and other personnel. In order that really satisfactory service may be rendered it is essential that hospitals command the support of well trained physicians and a community of adequate size. The guiding principle must always be the welfare of the patients. Hospitals have been developed coincidentally with the advance and progress in medicine in such methods and means of treatment as antitoxins, toxoids, serums and vaccines, and diagnostic and treatment apparatus, useful in the hands of experts but dangerous in the hands of the ignorant.

More than ever the use of these modern aids in medical practice requires preparation in the sciences fundamental to medicine, training in an approved medical school, an approved internship followed by postgraduate training, and experience to develop skill in examining patients, in making accurate diagnoses and in applying the particular form of treatment which the condition of the patient indicates. Because of these valuable aids in combating disease, hospitals have become more essential in the practice of medicine. Hospitals have reached a higher standard of development than ever before, but there are still further heights to attain in their service to humanity. No influence, either from within or from without, should be permitted to destroy their high educational, moral and professional standards.

## THE WAGNER BILL FOR MEDICAL CARE

On February 28 Senator Wagner of New York introduced into the Senate of the United States a bill, S 1620, entitled A Bill to provide for the general welfare by enabling the several states to make more adequate provision for public health, prevention and control of disease, maternal and child health services, construction and maintenance of needed hospitals and health centers, care of the sick, disability insurance, and training of personnel. The bill had been announced again and again in newspaper publicity since the day when Congress convened. Much secrecy surrounded its preparation and development. Apparently up to the moment of its introduction even Mr. Wagner himself and his office were not sure as to just what the bill would include. On one day the press would state that it was proposed to include compulsory sickness insurance. A few days later it would be rumored that such inclusion was not contemplated. Obviously it is the purpose of the measure to begin fulfillment of the so-called National Health Program, although the measure is, in many of its recommendations, exceedingly vague.

Elsewhere in this issue appears an analysis of this measure by the Bureau of Legal Medicine and Legislation of the American Medical Association. Essentially the measure embarks on a three year program providing more than \$98,250,000 the first year and subsequent grants in ensuing years, indeterminate in amount except in a few particulars but sufficient to make effective the purposes of the bill. The details of the sums allotted are shown in the tabulation (page 1000).

The House of Delegates of the American Medical Association, in considering the National Health Program, approved expansion of public health service where need could be shown, approved medical care to the indigent and to the medically indigent where need could be shown, and approved even expansion of hospital construction, provided the need could be demonstrated, recommending, however, utilization of existing facilities to the utmost before a new building program was authorized. The House of Delegates also approved the principle of assistance to the worker for temporary disability resulting from illness. Now the Wagner act goes far beyond these recommendations. First, it authorizes the expenditure of vast sums before the need has been shown, second, it expands tremendously the work of the Children's Bureau, the United States Public Health Service and the Social Security Board, without any demonstration that such expansion is warranted, third, it proposes to place the state health officers in a commanding position as far as concerns the dispensing of the funds allotted, subject only to approval of all plans by the federal agency to which the task is assigned. Vast funds are provided for the construction of hospitals and health centers and for their maintenance, notwithstanding the fact that there

is not yet available any dependable determination of the exact nature and extent of needs that prevail. Who can imagine for a moment that the money once appropriated will not be expended? Finally, the measure introduces the principle of allotment of federal money to the individual states for medical care, by the Social Security Board, without specifying the means to be used in the individual states for providing such service other than to demand the approval of the Social Security Board.

As is emphasized in the analysis made by the Bureau of Legal Medicine and Legislation, the advisory councils to be set up are vague as to their membership, their duties and their responsibilities. There is one criticism that is to be made above all others in relation to this proposed legislation, namely its extreme vagueness in the light of the vast sums of money to be dispensed and the great powers conferred on certain federal officers in the control of the spending, and particularly the decision as to which of the individual states shall benefit by the expenditures.

---

## INTERNSHIPS, RESIDENCIES AND FELLOWSHIPS

Hospital internships, residencies and fellowships have gained further prominence of late in view of their relation to the certification of specialists. Internships were first to become firmly established as an essential period of hospital training following graduation. They acquired official recognition in 1914, when 508 general hospitals were approved for intern training by the Council on Medical Education. Since that time there has been a steady expansion of educational facilities, until at present 7,373 internships are available in 734 approved hospitals.

Now the demand for interns exceeds the annual supply of medical graduates, many hospitals are unable to secure the required number of applicants. Even in the face of strong competition for desirable interns, additional hospitals are planning to enter the educational field, as evidenced by their application for approval as institutions suitable for the training of interns. As in other fields, the strong will survive, gradually a balance will be restored through the elimination of services that are poor in educational returns.

The certification of specialists, which has held the attention of the medical profession during the last few years, has wrought conspicuous changes in the field of graduate medical education. Most significant has been the rapid increase in number of residencies and fellowships, the change in length and character of training, the introduction of basic science requirements and the evident desire on the part of hospitals to supply instruction on an approved basis. A steadily increasing number of young physicians are seeking the direct approach to specialization without an intervening period of general practice. Their search for specialized training is

causing more and more hospitals to enter on courses of graduate instruction. Residencies are of comparatively recent origin and have not yet attained the degree of stability and uniformity which characterizes the intern field.

In 1927 a separate residency classification was established, when 278 hospitals and 1,776 individual residencies were approved. The rapid expansion of educational opportunities has increased the approved hospitals to 503 and the residencies and fellowships to 3,977. Last year the Council extended the residency classification to include fellowship training. In spite of the large number of approved positions there is no indication that a saturation point has been reached in any of the specialties.

Another development of profound significance is the close cooperation that has been established between the Council on Medical Education and Hospitals, the Advisory Board for Medical Specialties and the individual certifying boards. Cooperation has already been developed with the American Board of Radiology, the American Board of Pathology and the American Board of Anesthesiology. As soon as possible a similar procedure will be inaugurated with each of the remaining boards, that uniformity in the investigation and appraisal of educational opportunities may be accomplished. With the aid of the specialty boards a complete revision of the "Essentials of Approved Residencies and Fellowships" is in process. The educational requirements of individual specialties will then be more definite and more clearly apparent.

## Current Comment

### A COLOR TEST FOR MALARIA

After reviewing Henry's theory of immunity in malaria and Henry's melanoreaction, Proske and Watson<sup>1</sup> have described a protein tyrosine test which they consider valuable in the diagnosis of malaria. The principal reagents consist of sodium sulfate solution, sodium hydroxide solution, tyrosine standard solution and the phenol reagent of Folin and Ciocalteu. This test, when serums are used, they assert, gives a simple accurate colorimetric reading which obviates the necessity for a photometer, which was required by the Henry serodiagnostic test. The procedure is based on the fact that proteins possess a chromogenic property which can be measured quantitatively against the color produced by pure tyrosine in the presence of a phenol reagent. This chromogenic value is constant for a given protein and the intensity of the color produced can be used as a measure of the amount of protein examined. The tyrosine chromogenic index is determined by comparison with standards procured from pure tyrosine. As a result of the examination of more than 2,000 normal blood serums, these investigators

found that the tyrosine index for euglobulin fluctuates between 50 and 80 while that for serum from malaria patients ranges from 80 to 280 or higher. The test was found to be indicative of the presence of malaria in 97.4 per cent of known malaria cases examined as compared with 81.9 per cent positive thick blood films examined at the same time. Like the Henry test and its modifications this test, it is pointed out, is non-specific but its high sensitivity in malaria may make it a useful adjunct in the laboratory diagnosis of this disease and possibly in the differential diagnosis of other pathologic conditions characterized by an increase in serum euglobulin.

### REFRACTIVE ERRORS IN CHILDREN

A tabulation of the refractive errors observed in the right eyes of 1,481 children examined twice or more at varying intervals indicates, according to Ciocco,<sup>1</sup> that interesting changes take place in the frequency of stated refractive errors. The proportion of individuals with emmetropia (eyes needing no correction whatever) and mixed astigmatism did not alter, the frequency of hyperopia was reduced by almost 20 per cent, the number of cases of hyperopic astigmatism increased by about 40 per cent and the frequency of myopia and myopic astigmatism increased by about 70 and 65 per cent respectively. More than 75 per cent of the eyes with any of the main types of refractive errors however remained unchanged during the stated interval. When changes did occur, the nonastigmatic conditions (simple myopia and hyperopia) were transformed to astigmatism, while the astigmatisms changed back to the simple refractive errors. The chances of a change in type of refractive error appear to decrease with increase in the age of the children. Within the two and one half year interval, the age specific incidence rate of myopia was highest for the children from 10 to 11 years of age at the first examination and was lowest for the children of 14 years and over. For astigmatism, the age specific incidence rate was highest for children from 6 to 7 and from 12 to 13 years old, the lowest incidence of new cases of astigmatism was found among children of 14 years and over.

### DISEASE NOMENCLATURE

This year for the first time the Council on Medical Education and Hospitals included a question asking for the disease nomenclature used by hospitals. Of those which replied, 753 stated they were using the Standard Classified Nomenclature of Disease, now published by the American Medical Association, 1,063 stated they were using either the Ponton Alphabetical Nomenclature of Disease, the Bellevue Hospital or the Massachusetts General Hospital nomenclature, and 1,167 reported use of other classifications or none at all. Hence only 1,816 hospitals are employing what can be considered today as modern methods of classifying disease.

# ORGANIZATION SECTION

## THE WAGNER BILL FOR THE NATIONAL HEALTH PROGRAM AN ANALYSIS BY THE BUREAU OF LEGAL MEDICINE AND LEGISLATION

Senator Robert F. Wagner of New York, February 28, introduced a bill to carry into effect the recommendations of the Interdepartmental Committee to Coordinate Health and Welfare Activities, appointed by the President in August 1935. The bill, S. 1620, was referred to the Senate Committee on Education and Labor.<sup>1</sup> Although the bill is actually an amendment to the Social Security Act, the bill proposes that if it is enacted it be called the "National Health Act of 1939."

The Social Security Act imposes pay roll taxes to finance the payment of the old age benefits and unemployment compensation provided for by the act, but it imposed no taxes to pay for the other federal aid it provided, such as maternal and child health services, public health services, child welfare services, and services for crippled children. The cost of the services last named is paid for from the general revenues of the Country and raised by general taxation. The present bill proposes no payroll taxes or other taxes for raising the funds necessary to meet the expenses that its enactment would entail. All expenses are to be met by general taxation, federal and state.

### SCOPE OF BILL

This new bill, which will be referred to for convenience as the Wagner National Health Bill, proposes to amend and supplement the provisions of the Social Security Act in relation to the following matters:

- 1 Maternal and child health services
- 2 Services for crippled children
- 3 Administration of grants to states for maternal and child welfare
- 4 Public health work
- 5 Grants to states for hospitals and health centers
- 6 Grants to states for medical care
- 7 Grants to states for temporary disability compensation
- 8 Rules for the determination of the financial status of states

### MATERNAL AND CHILD HEALTH SERVICES

The state maternal and child health services for which grants-in-aid are now authorized by the Social Security Act are limited to services for the promotion of the health of mothers and children. The pending bill proposes to authorize such grants to enable states "to extend and improve services, supplies and facilities for promoting the health of mothers and children, and medical care during maternity and infancy, including medical, surgical, and other related services, and care in the home or in institutions, and facilities for diagnosis, hospitalization, and aftercare", and to develop more effective measures for carrying out such purposes, including the training of personnel.

<sup>1</sup> Senate Committee on Education and Labor. Elbert D. Thomas of Utah chairman. David I. Walsh of Massachusetts. James E. Murray of Montana. Vic Donahey of Ohio. Rush D. Holt of West Virginia. Claude Pepper of Florida. Allen J. Ellender of Louisiana. Josh Lee of Oklahoma. Lister Hill of Alabama. William E. Borah of Idaho. Robert M. LaFollette Jr. of Wisconsin. James J. Davis of Pennsylvania. Robert A. Taft of Ohio.

### CRIPPLED CHILDREN

The Social Security Act now authorizes grants to enable the states to extend and improve services for locating crippled children and for providing medical, surgical, corrective and other services and care, and facilities for diagnosis, hospitalization and aftercare, for children who are crippled or who are suffering from conditions which lead to crippling. The Wagner National Health Bill proposes to enlarge such grants so as to authorize their use to enable states "to extend and improve services, supplies, and facilities for the medical care of children, and services to crippled children and other physically handicapped children in need of special care, such services and facilities to include medical, surgical, corrective, and other related services and care in the child's home or in institutions, and facilities for diagnosis, hospitalization, or other institutional care, and aftercare", and to develop more effective measures for carrying out such purposes, including training of personnel.

### MATERNAL AND CHILD WELFARE GENERALLY

The Social Security Act now authorizes the chief of the Children's Bureau to make such studies and investigations as will promote the efficient administration of the provisions of the act relating to grants to states for maternal and child welfare. The pending bill proposes to enlarge this so as to authorize also "demonstrations" and provision for the training of personnel.

### EXTENSION OF PUBLIC HEALTH SERVICE

For the purpose of assisting states, counties, health districts and other political subdivisions of the States in establishing and maintaining adequate public health services, including the training of personnel, the Social Security Act authorizes appropriations from which allotments are made by the Surgeon General of the Public Health Service. The Wagner National Health Bill proposes to limit such allotments to states and to authorize the making of such allotments "to extend and improve public-health work, including services, supplies, and facilities for the control of tuberculosis and malaria, for the prevention of mortality from pneumonia and cancer, for mental health, and industrial hygiene activities," and for the development of more effective measures for carrying out such purposes, including the training of personnel. The Social Security Act authorizes an appropriation for the investigation of disease and problems of sanitation by the Public Health Service, and the Wagner National Health Bill proposes to extend such authority so as to promote the use of the appropriations so authorized for the purpose of making "demonstrations" and for the training of personnel. The Wagner National Health Bill proposes to authorize the appointment of additional commissioned officers in the U. S. Public Health Service in accordance with law but without regard to the limitation as to number and research qualifications, including not to exceed four assistants to the Surgeon General.

The President, it is proposed, is to be authorized to change the names and reallocate the existing divisions of the Public Health Service and to create such additional administrative divisions as he may deem necessary to carry out the purposes of the act.

#### DETERMINATION OF ALLOTMENTS TO STATES

Various methods are proposed in the Wagner National Health Bill for determining the proportions of available funds that may be allotted to the several states. Allotments for maternal and child health services are to be determined in accordance with the rules and regulations prescribed by the chief of the Children's Bureau with the approval of the Secretary of Labor, the following factors being taken into consideration: (1) the total number of births in the latest calendar year for which the Bureau of the Census has available statistics, (2) the number of mothers and children in need of the services, (3) the special problems of maternal and child health and (4) the financial resources of the state. The financial resources of each state are to be measured by per capita income according to the inhabitants thereof as determined jointly by the Secretary of the Treasury, Secretary of Labor and the chairman of the Social Security Board annually.

Allotments for medical services for children and services for crippled and other physically handicapped children are to be determined in accordance with rules and regulations prescribed by the chief of the Children's Bureau with the approval of the Secretary of Labor, taking into account (1) the child population, (2) the number of children in each state in need of the services, (3) the special problems of medical care of children and (4) the financial resources of the state, determined as described.

Allotments to the several states for public health work are to be made in accordance with rules and regulations prescribed by the Surgeon General of the Public Health Service with the approval of the Secretary of the Treasury, taking into consideration (1) the population, (2) the number of individuals in need of the services, (3) the special health problems and (4) the financial resources of the state, determined as described.

Allotments to the states for hospital and health centers are to be made by the Surgeon General in accordance with rules and regulations prescribed by him, with the approval of the Secretary of the Treasury, which take into consideration (1) the needed hospitals and (2) the financial resources, determined as stated.

Allotments for medical care are to be determined in accordance with rules and regulations prescribed by the Social Security Board, taking into consideration (1) the population, (2) the number of individuals in need of the services, (3) the special health problems and (4) the financial resources.

The allotment to a state for temporary disability compensation is to be made only if that state has a plan for such compensation approved by the Social Security Board. The amount that may be paid is based on the sums expended as temporary disability compensation under the state plan. These payments are in the nature of supplementary unemployment compensation and so much as is to be paid by the federal government is to be taken from the general revenues of the country and not to be taken from a payroll or other similar tax.

#### NEW SERVICES

The Wagner National Health Bill proposes to authorize grants for three purposes that are not covered by the Social Security Act: (1) to provide and maintain hospital accommodations, (2) to provide medical care and (3) to provide temporary disability compensation.

#### HOSPITALS AND HEALTH CENTERS

Grants are proposed under the pending bill to enable the Surgeon General to allot to the several states money to enable them to construct and improve governmental hospitals where needed, to assist the states for a period of three years in defraying the operating cost of added facilities, and to develop more effective measures for providing hospitals. No provision is made whereby, by grant or loan, any nongovernmental charitable hos-

*Appropriations Proposed to Be Authorized by S 1620,  
the Wagner National Health Bill*

Purpose	Fiscal Year 1940	Fiscal Year 1941	Fiscal Subsequent Year 1942	Fiscal Years
Title V Part 1 Maternal and child health services	\$3,000,000	\$3,000,000	\$5,000,000	No limit
Title V Part 2 Medical services for chil- dren for crippled children and for other physically handicapped children	15,000,000	2,000,000	2,000,000	No limit
Title V Part 5 Administration	2,000,000	No limit	No limit	No limit
Title VI Part 1—Public Health Work				
(a)—Payments to states	15,000,000	2,000,000	20,000,000	No limit
(b)—Administration	1,500,000	No limit	No limit	No limit
Title VI Part 2 Investigations by Public Health Service	7,000,000	3,000,000	4,000,000	No limit
Title VII				
Grants for general hospi- tals	8,000,000	50,000,000	100,000,000	No limit
Grants for mental and tuberculosis hospitals	No limit	No limit	No limit	No limit
Administration	1,000,000	No limit	No limit	No limit

Title XIV				
Grants for temporary dis- ability compensation	10,000,000	No limit	No limit	No limit
Administration	2,000,000	No limit	No limit	No limit

pital can be used in making improvements or extensions or the construction of new hospitals of this class promoted. The term "hospital" is defined to include "health, diagnostic, and treatment centers, institutions, and related facilities."

State plans for the construction of hospitals in order to be approved by the Surgeon General must provide for financial participation by the state and include provisions similar to the provisions on which the approval of state plans for other purposes covered by this bill is conditioned. They must provide in addition, however, "such methods of administration as are found by the Surgeon General of the Public Health Service to be necessary for the efficient operation of the plan", provide that ownership of real estate, improvements and equipment be vested in the state or its political subdivisions, and provide such safeguards as may be necessary to assure satisfactory title, location, design, construction and equipment. Such plans must provide, too, a system of financial support which will give reasonable assurance of continuing maintenance of added hospitals and of their potential availability to all

groups of the population in the designated area subject only to the suitability of the hospitals for particular diseases and conditions and to the financial arrangement for payment for service. Such plans must provide that wages paid or to be paid laborers and mechanics employed in the construction of hospitals are not less than the wages paid in the locality for work of a similar nature. The Surgeon General is to be authorized to utilize the Federal Emergency Administration of Public Works or, on the termination thereof, another appropriate agency of the United States designated by the President, for the purpose of reviewing the title, location, plans and specifications for the construction, alteration and repair of buildings and equipment, and of supervising the awarding and performance of contracts pursuant to plans approved by the Surgeon General. Funds made available for defraying the operating cost of added facilities are to be paid for at the rate of \$300 per added bed for general and tuberculosis hospitals and \$150 per added bed for mental hospitals during the first year of operation, two thirds of these amounts, respectively, for the second year of operation, and one third of these amounts, respectively, for the third year of operation.

#### PROVISION OF MEDICAL CARE

Allotments to the several states to enable them to provide medical care are to be made under authority of the Social Security Board. They are intended to extend and improve medical care, including all services and supplies necessary for the prevention, diagnosis and treatment of illness and disability and to develop more effective measures for providing such care, including the training of personnel. These grants of federal money to the several states are to enable them to extend and improve medical care and are to be made on the basis of state plans approved by the Social Security Board. The bill is silent as to the permissible extensions and improvements of medical care that a state may make and as to whether such care shall be provided through a state medical service, similar to the public educational system, or by a system of state health insurance, or by payment for services on the fee basis.

#### TEMPORARY DISABILITY COMPENSATION

The provisions of the Wagner National Health Bill relating to grants to states for temporary disability compensation are intended to assist them in "the development, maintenance, and administration of plans for temporary disability compensation" and are to be administered by the Social Security Board on the basis of plans submitted by the several states and approved by the board. The term 'temporary disability compensation' is defined to mean "cash benefits payable to individuals for not more than fifty-two weeks with respect to their disability and not arising out of or in the course of their employment," but agricultural labor, domestic service in a private home, and casual labor in the course of an employer's trade or business does not come within the definition or within the benefits of the act, nor do merchants or mechanics operating on their own account.

#### CONDITIONS UNDER WHICH FEDERAL GRANTS MAY BE OBTAINED

The conditions laid down in the Wagner National Health Bill with which a state must comply in order to obtain the supposed benefits of the act are more

rigid than the conditions imposed by the Social Security Act, except with respect to grants to states for temporary disability compensation, which stand in a class by themselves.

Insistence has been placed on the provision of methods of establishing and maintaining standards of medical and institutional care and of remuneration for such care, such methods to be prescribed by the state agency after consultation with such professional advisory committees as the state agency may establish. Each state must provide, too, for an advisory council or councils, composed of members of the professions and agencies, public and private, that furnish services under the state plan, and other persons informed on the need for, or provision of, maternal and child health services. No limitation is placed on the number of such councils or on the number of members and their distribution as among the different classes eligible for membership, and no definition is given as to the nature and extent of their advisory authority. Federal advisory councils of similarly indefinite character are proposed for the chief of the Children's Bureau, the Surgeon General of the Public Health Service and the Social Security Board. Each of the officers and the agency named is to be authorized to appoint an advisory council or councils analogous to those required to be appointed by each state participating in any of the benefits proposed in this bill. Rule making likewise is given a prominent place in the bill, since a state plan with respect to any of the benefits named, except that for temporary disability compensation, must authorize the state agency "to make and publish such rules and regulations as are necessary for efficient operation of the services, having special regard for the quality and economy of the service," and the chief of the Children's Bureau, the Surgeon General of the Public Health Service, the Federal Emergency Administrator of Public Works and the Social Security Board is each to be authorized to make and publish rules and regulations. What the nature of such rules and regulations is to be and the manner of their enforcement are not disclosed.

#### AUTHORIZED APPROPRIATIONS

The accompanying table presents the appropriations that the Wagner National Health Bill proposes to authorize.

---

#### CLINICS VERSUS FREE CHOICE IN AUSTRIA

Even Nazi Germany does not consider clinics and contract physicians preferable to a system of free choice. In an article on the Introduction of German Sickness Insurance into Austria, Dr. Paul Petersilie, writing in the *Deutsches Aerzteblatt* (69:49 [Jan 14] 1939), emphasizes the fact that one of the first changes to be made in Austria was the abolition of the clinics and the district physicians in Vienna.

Under the clinic system contract physicians were required to maintain regular hours. When physicians were changed "a patient who in the course of a continuous treatment, was required to visit the clinic more than once could not depend on always being treated by the same physician." In Germany physicians had already decided that this sort of medical care was ineffective and that clinic treatment and the maintenance of contract physicians were not in the interests of the insured. The German sickness insurance administration has insisted that in the interests of the insured the clinics should be abolished and free choice of physician should be introduced universally throughout Austria.

## OFFICIAL NOTES

## CONFERENCE ON MEDICAL PATENTS

All class A medical schools and universities having medical schools, all manufacturers who have products before the Council on Pharmacy and Chemistry, all foundations having patents, and individuals who have expressed special interest have been invited to a conference on medical patents at the headquarters building of the American Medical Association in Chicago March 16. The response has been gratifying. Well over a hundred of these representatives as well as members of the Council on Pharmacy and Chemistry and members of the Board of Trustees have indicated their intention to participate. The program is not completed but the following have accepted invitations to speak.

## Opening Statement on Medical Patents

DR ROGER I. LEE, member of the Board of Trustees and member of the Harvard Corporation

## The Administration of Medical Patents for the Public Welfare

DR GLADYS DICK of the Scarlet Fever Committee

MR F. LORNE HUTCHISON, Secretary of the Insulin Committee, University of Toronto

## Manufacturers' Point of View on Medical Patents in Relation to Public Welfare

DR JOHN F. ANDERSON, President of American Drug Manufacturers' Association and Vice President of E. R. Squibb & Sons

DR A. W. LESCOHIER, President of Parke, Davis & Co.

## The Public's Stake in the Administration of Medical Patents

EARL SHEPARD JOHNSON, Assistant Professor of Sociology, University of Chicago

## Medical Patents and the Licensing System from the Point of View of the Council on Pharmacy and Chemistry

DR TORALD SOLLMANN, Chairman of the Council on Pharmacy and Chemistry and Professor of Pharmacology at Western Reserve University School of Medicine

## THE ST LOUIS SESSION

## Program of Entertainment by Woman's Auxiliary

Entertainment for all women attending the St. Louis session of the American Medical Association and of the national Woman's Auxiliary, May 15-19, has been arranged by the Committee on Women's Activities.

St. Louis women and pre-convention guests are requested to register in advance at Women's Headquarters at Hotel Chase in St. Louis Saturday May 13 between 1 and 4 p. m. or on Sunday May 14 between 10 a. m. and 4 p. m. All visiting women are requested to register as soon as possible after arrival.

The preliminary program is as follows:

## SUNDAY, MAY 14

10 a. m. to 4 p. m. Registration. Hostess Committee to receive visitors in afternoon.

4 p. m. to 7 p. m. Tea for the National Board in honor of Mrs. Charles C. Tomlinson at the residence of Mrs. Willard Bartlett.

## MONDAY, MAY 15

9 a. m. National board meeting, Empire Room, Hotel Chase.

1:30 p. m. to 4:45 p. m. Visit to St. Louis County private gardens and tea (complimentary). Bus fare 75 cents.

## TUESDAY, MAY 16

9 a. m. to 12. Opening of convention of Woman's Auxiliary.

General session of Woman's Auxiliary, Empire Room, Hotel Chase.

12:30 p. m.

1:45 p. m.

4 p. m.

8 p. m.

9 a. m.

1 p. m.

2:30 p. m.

Wednesday Evening

9 a. m.

10 a. m.

12:30 p. m. to 3:30 p. m.

7 p. m.

9 p. m.

Luncheon, St. Louis Woman's Club \$1.25.

Optional tours, \$1.

(a) Park area.

(b) Arts tour.

Tea (complimentary). Guests of St. Louis University Woman's Club.

Opening General Meeting of the American Medical Association at Municipal Auditorium.

(Special busses from Hotel Chase to Auditorium and return, 50 cents round trip.)

## WEDNESDAY, MAY 17

Annual Meeting of Woman's Auxiliary, Empire Room, Hotel Chase.

Annual luncheon, Chase Club \$1.25.

Exhibits and music, Empire Room. Conferences.

Reception, supper and program (complimentary). The Woman's Auxiliary invites all visiting ladies. Motion pictures, U. S. seal fisheries and fur fashion show.

## THURSDAY, MAY 18

Forenoon. Post-convention meetings.

Executive Committee meeting.

Board of Directors meeting.

Mississippi River steamboat trip for men and women, \$1. Usual light refreshments available at reasonable prices. Transportation by special bus for those who buy tickets in advance, 50 cents.

Annual Bring Your Husband Dinner, \$2.

President's Reception and Ball. Hosts, American Medical Association.

(Bus arrangements from Hotel Chase to Hotel Jefferson, 25 cents.)

## FRIDAY, MAY 19

Women's golf round and blind bogey. Trophies and prizes provided.

## The William Beaumont Exhibit and the Exhibit of Medals

Many visitors to St. Louis during the Annual Session of the American Medical Association will be interested in the collection of letters and notebooks relating to Dr. William Beaumont, the pioneer American physiologist, who served in St. Louis as an army surgeon and later became a busy practitioner of medicine in St. Louis. Beaumont was one of the early presidents of the St. Louis Medical Society. The most important scientific collection of Beaumontiana in existence can be seen at the Library of Washington University School of Medicine, Euclid Avenue and Kingshighway.

At the Library of the St. Louis Medical Society will be a display of medals, plaquettes and coins in the Hugo W. Bartsch Room on the library floor. This exhibit consists of tokens of honors conferred on physicians and commemorative disks of epoch-making contributions to medicine. Some of these are curious "touch pieces," coins that were given to such victims of the King's Evil (scrofula or struma) when the rulers of Great Britain "touched" such patients to cure them by the "divine power of royalty." Plastic disks and plates are actually miniature monuments to achievements in medical science. They are not ordinarily exhibited to the public. It is gratifying that their owners have lent their possessions to this unique cooperative display.

## RADIO BROADCASTS

The fourth series of programs broadcast in dramatic form portraying fictitious but typical incidents of significance in relation to health by the American Medical Association and the National Broadcasting Company, entitled "Your Health," began Wednesday October 19 and will run consecutively for thirty-four weeks. The program is broadcast each Wednesday over the blue network of the National Broadcasting Company at 2 p. m. eastern standard time (1 p. m. central standard time, 12 noon mountain time, 11 a. m. Pacific time).<sup>1</sup>

These programs are broadcast on what is known in radio as a sustaining basis, that is, the time is furnished gratis by the radio network and local stations and no revenue is derived

from the programs. Therefore, local stations may or may not take the program, at their discretion, except those stations which are owned and operated by the National Broadcasting Company.

The next three programs to be broadcast, together with their dates and their topics, are as follows:

March 15	Guarding Fresh Foods
March 22	Auditing the Health Record
March 29	Animal Diseases Transmitted to Man

<sup>1</sup> Owing to program conflicts there will be no Chicago broadcast of the network program. Instead a recording of the program will be broadcast over station WENR at 8 p. m. each Wednesday. This recording will be an identical rebroadcast of the network program broadcast earlier the same day.

## MEDICAL LEGISLATION

### MEDICAL BILLS IN CONGRESS

*Changes in Status*—S 685, proposing to create a Division of Water Pollution Control in the United States Public Health Service, has been reported to the Senate without amendment. S 1464 has been reported to the Senate, with amendment, proposing to extend the facilities of the United States Public Health Service to active officers of the Foreign Service of the United States. For illness or injury directly attributable to service on foreign assignment, medical and surgical treatment and hospitalization by the United States Public Health Service will be supplied, it is contemplated, at government expense. For illness or disability not the direct result of foreign service suffered by any officer or American employee of the Foreign Service only, any dependent member of the family of such officer or employee, such illness or injury having originated while on foreign station, medical and dental treatment and hospitalization may be furnished by the United States Public Health Service at a cost to the officer or employee in accordance with rates established by regulations of the Surgeon General of the Public Health Service. H R 1776 has been reported to the House, with amendment, providing for the assignment of medical officers of the United States Public Health Service for duty on vessels of the Coast and Geodetic Survey. H R 4425 has been reported to the House, without amendment, proposing to provide for reorganizing agencies of the government.

*Bills Introduced*—S 1540, introduced by Senator Overton, Louisiana, proposes to increase the compensation of members of the National Advisory Health Council not in the regular employment of the government from \$5 to \$25 per diem. S 1582, introduced (by request) by Senator Bulow, South Dakota, proposes to authorize the President to bestow a Meritorious Service Medal on any civil officer or employee of the United States, including commissioned officers of the United States Public Health Service and of the Coast and Geodetic Survey, for the performance of an outstanding act or service involving great physical bravery or heroism, or for the performance of a service to the government or to humanity characterized by exceptional merit and involving a high degree of labor or effort above and beyond the ordinary and usual requirements of his office. S 1615, introduced by Senator Sheppard, Texas, proposes to authorize the appointment of female dietitians and female physiotherapy and occupational therapy aides in the Medical Department of the Army. S 1620, introduced by Senator Wagner, New York, proposes to provide for the general welfare by enabling the several states to make more adequate provision for public health, prevention and control of disease, maternal and child health services, construction and maintenance of needed hospitals and health centers, care of the sick, disability insurance, and training of personnel. S 1691, introduced by Senator Clark, Missouri, proposes to prevent the pollution of the navigable waters of the United States. H R 4311, introduced by Representative Gearhart, California, proposes to prohibit the importation of dairy products produced from milk or cream other than from cows either accredited free of bovine tuberculosis or under test for bovine tuberculosis. H R 4314 introduced (by request) by Representative Mansfield, Texas, proposes to provide federal aid to states in the control of water pollution

and to create a Division of Water Pollution Control in the United States Public Health Service. H R 4401, introduced by Representative Tenerowicz, Michigan, proposes to authorize an appropriation of \$250,000 to provide a 250 bed patient addition to the veterans' hospital at Dearborn, Mich. H R 4530, introduced by Representative Buckley, New York, proposes to provide that, for pension purposes, any female trained nurse who served in Red Cross Auxiliary Numbered 3 in the Philippine Islands during the Spanish-American War shall be considered to have been in the active military service in the United States. H R 4585, introduced by Representative Rogers, Massachusetts, proposes to amend the National Cancer Institute Act so as to authorize an additional appropriation of \$2,300,000 for the fiscal year ending June 30, 1940, and for each fiscal year thereafter such sums as may be necessary, to assist states, counties, cities or other political subdivisions to extend and improve measures through public and private institutions and organizations for the diagnosis, treatment and control of cancer, including the provision of hospital, diagnostic, clinic and other facilities for the diagnosis and treatment of persons suffering from cancer or suspected of suffering from this disease. H R 4639, introduced by Representative Rogers, Massachusetts, proposes to provide prosthetic appliances to certain veterans suffering from non-service connected disabilities. H R 4652, introduced by Representative Voorhis, California, proposes to provide hospitalization and domiciliary care to retired enlisted men of the Army, Navy, Marine Corps and Coast Guard who are war veterans, on parity with other war veterans. H R 4685, introduced (by request) by Representative May, Kentucky, proposes to provide medical treatment, hospitalization and allowances for members of the National Guard, Officers' Reserve Corps and Enlisted Reserve Corps who are injured or become ill while on active duty under proper orders in time of peace. H R 4747, introduced by Representative Tenerowicz, Michigan, proposes that for federal income tax purposes a taxpayer may deduct, up to \$500, all the ordinary and necessary expenses paid or incurred during the taxable year for hospitals, physicians, medicines and expenses incident to burial.

### District of Columbia

*Bills Introduced*—H R 4312, introduced by Representative Hull, Wisconsin, proposes to amend the Code of the District of Columbia to provide for the organization and regulation of cooperative associations. The bill provides "In the case of an association formed hereunder which arranges the rendering to its members of licensed professional services on a nonprofit basis, said association shall not be subject to the insurance laws, shall not be construed as being in violation of any rule against corporate practice of professions, or in violation of statutes regulating licensure of professions." H R 4569, introduced by Representative Shanley, Connecticut, proposes to provide for the issuance of a license to practice naturopathy in the District of Columbia to Edward F. Grillo. H R 4732 and H R 4733, introduced by Representative Short, Missouri, propose, respectively, to provide for the issuance of a license to practice chiropractic in the District of Columbia to George M. Corriveau and to Laura T. Corriveau.

**A Special Flea Laboratory**—A two story building is under construction at the University of California Medical Center, San Francisco, to be used for the study of the flea. The new laboratory will play a major part in new investigations into sources of bubonic plague among animals and other problems, according to the state medical journal

**Society News**—At a meeting of the Kern County Medical Society in Bakersfield January 19 Dr James C Negley, Glendale, among others, spoke on treatment of bladder neck obstructions—The Ventura County Medical Society was addressed January 10 by Drs Arthur Elmer Belt and Alvin W Folkenberg, Los Angeles, on "Gonorrhea and Its Complications" and Treatment of Gonorrhea by Sulfanilamide and Heat' respectively

**Personal**—Dr Cornelius Martin Mills, Oakland, has been appointed chief of the crippled children's services of the California State Department of Public Health. He will have charge of the department's activities under the California Crippled Child Act and those for the relief of the physically handicapped made possible through the provision of social security funds—Alfred E Maffly, superintendent of the Berkeley General Hospital, Berkeley, was elected president of the East Bay Hospital Conference January 8. He has been secretary for the past four years. The conference includes the following hospitals: Alameda County, Alameda Sanatorium, Alta Bates, Berkeley General, Children's, Cowell Memorial, East Oakland, Fairmount, Samuel Merritt, Peralta, Providence and Richmond Cottage—Dr Edwin L Bruck has been appointed a member of the advisory council to the San Francisco Department of Health, succeeding Dr William C Voorsanger

### ILLINOIS

**Twenty WPA Laboratories Planned**—Twenty laboratories will be constructed by the WPA for the state department of health, according to a recent announcement. Subject to federal approval the laboratories will be situated where facilities are inadequate and will not compete with or duplicate existing public or private laboratories. They will not be used for treatment, it was said

### Chicago

**Syphilis Course Postponed**—The graduate course in syphilis, sponsored by the department of dermatology of the University of Illinois College of Medicine in cooperation with other departments, has been postponed on account of the epidemic of influenza, according to an announcement from the dean. The course was to begin February 27 but has been postponed to April 4. Details appeared in THE JOURNAL February 18, page 653

**The Christian Fenger Lecture**—Bradley M Patten, Ph D, professor and director of the department of anatomy, University of Michigan Medical School, Ann Arbor, will deliver the third Christian Fenger lecture of the Chicago Pathological Society and the Institute of Medicine of Chicago March 24 at the Palmer House. His subject will be "Microcinematographic and Electrocardiographic Study of the First Heart Beats and the Beginning of the Circulation in Living Embryos," illustrated with micromoving pictures and lantern slides

### IOWA

**Advisory Committee to Board of Health**—Dr Erwin J Gottsch, Shenandoah, was recently appointed by the governor to succeed Dr Charles E Irwin, Woodward, as a member of the state board of health advisory committee. Other members of the committee, who were reappointed, are Drs Walter A Sternberg, Mount Pleasant, Walter J Connell, Dubuque, Edward M Myers, Boone, and Herbert E Stroy, Osceola

**Society News**—A special meeting of the Des Moines Academy of Medicine and the Polk County Medical Society, Des Moines, March 14, will be addressed by Drs Donald R Black and George H Thiele, both of Kansas City, Mo, on "Pathology and Physiology of the Pancreas and Liver as Applied to the Treatment of Diabetes" and "Clinical Manifestations of Anorectal Diseases and Their Treatment" respectively

### KANSAS

**Annual Spring Clinical Assembly**—The Sedgwick County Medical Society will conduct its third annual spring clinical assembly in Wichita March 21-22. The speakers will include

Dr Nathan A Womack, St. Louis, Cancer of the Breast  
Dr Hyman I Spector, St. Louis, Treatment of Pulmonary Tuberculosis with Special Emphasis on Collapse Therapy  
Dr Erastus S Edgerton, Regional Ileitis  
Dr Earl D Carter, The Normal Fundus with Some Variations in Disease  
Dr Edwin H Terrill, Cardiac Enlargement—A Method for Its Determination  
Dr Arthur E Bence, Postreduction Treatment of Fractures  
Dr Abraham E Hiebert, Burns  
Dr Joseph V Van Cleave, Skin Cancer  
Dr Vincent L Scott, Pyloric Spasm and Stenosis  
Dr Vern L Pauley, Comparison of Transurethral Resection with Prostatectomy  
Dr William R Houston, Austin, Texas, Spasm in Plain Muscle.  
Dr Henry N Tihen, Pneumonia—New Concepts in Therapy  
Dr Andrew Allen Olson, Bronchial Asthma  
Dr Howard C Curtis, Murihuana  
Dr Ray A West, Management of Pelvic Infections  
Dr Ralph L Drake, A Case of Multiple Personality (motion picture)

A symposium on sulfanilamide will be presented by Drs Harold W M Palmer, Frank L Menehan, George B Morrison and Ernest M Seydell. At the banquet Dr Spector will speak on Differential Diagnosis of Hemoptysis" and Dr Womack, "Pathology of Cancer of the Lung"

### KENTUCKY

**State Hospital Heads Appointed**—Dr Addie M Lyon, Louisa, recently health officer of Lawrence County and formerly superintendent of the State Institution for the Feeble-minded at Frankfort, has been appointed superintendent of the Western State Hospital, Hopkinsville. Dr Lyon graduated from the University of Louisville School of Medicine in 1912 and practiced in Sandy Hook for fourteen years. From 1926 to 1936 he was in charge of the Institution for the Feeble-minded. Dr William R Summers, acting superintendent of Central State Hospital, Lakeland, since September 1938 has been permanently appointed. Dr Summers has previously served on the staffs of the Western State Hospital at Hopkinsville and at the East Louisiana State Hospital, Jackson, La. All three state hospitals are now under new administrations in accordance with the terms of the Chandler-Wallis law enacted in 1938, with Dr Joseph G Wilson, Frankfort, formerly of the U S Public Health Service, as director of the division of hospitals of the state department of welfare. Dr Floyd K. Foley was recently appointed superintendent of the Eastern State Hospital at Lexington

### MARYLAND

**Ordinance Requires Ratproofing**—An ordinance has been passed in Baltimore as a part of a rat control program providing for the ratproofing of all buildings hereafter erected in the city for the protection of public health and to prevent the introduction or spread of rat-borne diseases

**Personal**—Mrs Margaret Reed Lewis of the department of embryology of the Carnegie Institution at Johns Hopkins University, Baltimore, received the honorary degree of doctor of laws at the recent fiftieth anniversary celebration at Goucher College—Dr Henry E Sigerist, director of the Institute of Medicine, Johns Hopkins University School of Medicine, Baltimore, will lecture during August, September and October in universities of the Union of South Africa, under a visiting lectureship, according to the newspapers—Dr Henry F Buettner, school medical examiner, Baltimore health department has been appointed full time medical health officer in Baltimore bringing the total of such appointments in the city to five. Dr Buettner, a graduate of the University of Mar-

land School of Medicine, was appointed a part time health officer in the department April 1, 1920. He is also a member of the faculty of his alma mater.

### MASSACHUSETTS

**Symposium on Virus and Rickettsial Diseases**—A short course of lectures, clinics and demonstrations on the virus and rickettsial diseases, with special emphasis on their public health significance, will be presented at the Harvard School of Public Health, Boston, June 12-17. Lectures on the etiology, epidemiology and methods of control of these diseases, given by members of the faculties and former students of the Harvard School of Public Health and the medical school, will occupy five mornings. Special clinics and demonstrations will be given each afternoon. In some instances these demonstrations will be continued through the week, so that all the members of the symposium can attend. On the last morning a panel discussion will be held on the three main topics presented in the symposium. The fee for the course will be \$25, payable at any time up to June 12. Enrolment should be arranged before June 1 as facilities for many of the clinics and demonstrations are limited. The lectures will be published later in a single volume, which will be sent to each person who has registered for the course. Further information may be obtained from the secretary of the school of public health, 55 Shattuck Street, Boston.

### MICHIGAN

**Tuberculosis in School Teachers**—After finding a number of unsuspected cases of tuberculosis in school teachers of Jackson, the Jackson County Medical Society January 17 unanimously adopted a recommendation that each school teacher in Jackson County be required to furnish a health certificate from a family doctor before a contract is renewed. The certificate should include a negative Kahn test and either a negative Mantoux test or a negative report on an x-ray examination of the chest, the society recommended. The secretary was instructed to mail a copy of this recommendation to the board of education of the city of Jackson, the state of Michigan Board of Education, the Michigan State Department of Health and the secretary of the Michigan State Medical Society.

### MINNESOTA

**The Clarence M. Jackson Lecture**—Dr. Arthur E. Hertzler, Halstead, Kan., will deliver the sixth annual Clarence M. Jackson Lecture of the Northrop Memorial Auditorium Minneapolis, March 16. His subject will be 'The Morphology of the Thyroid Gland'. The lecture is under the auspices of the Hennepin County Medical Society.

### NEW JERSEY

**Society News**—Dr. Morris A. Weinstein, Philadelphia, addressed the Atlantic County Medical Society, Atlantic City, February 10 on 'Streptococcal Otitic Meningitis'.—Drs. Israel S. Wechsler and Cornelius G. Dyke, New York, and Leo M. Davidoff, Brooklyn, addressed the Academy of Medicine of Northern New Jersey February 16 on 'Modern Viewpoints in the Diagnosis of Brain Tumors'. Dr. Henry E. Sigerist, Baltimore, gave an address to the public at the academy February 18 on 'Medicine as a Social Institution'.—Dr. William Bates, Philadelphia, addressed the Gloucester County Medical Society, Woodbury, February 16 on 'The Pseudosurgical Abdomen'.—Speakers before the Essex County Medical Society in Newark February 9 were Drs. Russell L. Cecil on 'Serum Treatment of Pneumonia', Arthur M. Fishberg 'The Heart in Pneumonia' and Edgar A. Lawrence, 'Chemotherapy of Pneumonia'. All are of New York.

### NEW YORK

**Record Low Mortality Rate**—The lowest general mortality rate ever experienced for New York was revealed in the annual report of health conditions for 1938, issued by the state department of health. The general death rate was 10.8. The birth rate, 14 per thousand of population was the highest in four years. Infant mortality (41 per thousand live births) was 9 per cent less than the minimum reached in 1937. Maternal mortality (36 deaths per 10,000 of total births) indicated a reduction of 41 per cent in only five years. The leading cause of death at all ages was the group of heart diseases with a rate of 350.4, an increase of 1 per cent over the preceding year. Cancer was second in importance with a rate of 148.9, an increase of 2 per cent. Except for these two diseases all other important causes of death had favorable mortality rates. The influenza rate (3.5) was the lowest in the

history of the state, that for pneumonia (61.3) was 27 per cent lower than that of the previous year. Other record low rates were tuberculosis, all forms, 48.2, acute and chronic nephritis, 67.9, typhoid and paratyphoid, 0.4. The death rate from all types of accidents (62.5) has never been lower, according to the report. The most striking reduction took place in automobile accidents, the rate (18) was the lowest in sixteen years and was 21 per cent lower than that for 1937. The September hurricane was responsible for forty-eight deaths. For the first time in eleven years, deaths from diabetes decreased, the rate was 34.9. The appendicitis death rate (11) has not been equally low since 1910.

### New York City

**Sixth Harvey Lecture**—Prof. K. Linderstrom-Lang of the Carlsberg Laboratory, Copenhagen, Denmark, will deliver the sixth Harvey Lecture of the current series at the New York Academy of Medicine March 16, on 'Distribution of Enzymes in Tissue and Cells'.

**Dr. Van Slyke to Receive Gibbs Medal**—Donald Dexter Van Slyke, Ph.D., member of the Rockefeller Institute for Medical Research, is to receive the twenty-eighth Willard Gibbs Medal of the Chicago section of the American Chemical Society in recognition of his work on chemistry of the blood, it was announced February 24. Dr. Van Slyke is 55 years old and received his doctorate at the University of Michigan, Ann Arbor, in 1907, when he joined the staff of the Rockefeller Institute. His work has concerned chemistry and physiology of proteins and amino acids, laws of enzyme action, methods for analysis of blood, gasometric analyses, respiratory and renal functions, physical chemistry of blood, diabetes, nephritis and quantitative clinical chemistry. The medal will be awarded at a meeting in Chicago May 19.

### NORTH CAROLINA

**Syphilis Clinic at Duke University**—A graduate clinic on the diagnosis and treatment of syphilis will be held at Duke University School of Medicine, Durham, March 24-25 under the auspices of the university and the North Carolina State Board of Health. The principal speakers will be Drs. Thomas Parran, surgeon general, U. S. Public Health Service, Washington, D. C., Joseph Earle Moore, Baltimore, John H. Stokes and Norman R. Ingraham, Philadelphia, Harold N. Cole, Cleveland, Paul A. O'Leary, Rochester, Minn., and Philip C. Jeans, Iowa City.

**Extension Course in Medicine**—A course of lectures sponsored by the University of North Carolina extension division has been presented at Charlotte during recent weeks. The speakers were:

Dr. Paul D. White, Boston, heart disease, January 16.  
Dr. George B. Eusterman, Rochester, Minn., diseases of the liver and gallbladder, January 24.  
Dr. Elliott P. Joslin, Boston, diabetes, January 31.  
Dr. Jonathan C. Meakins, Montreal, Canada, chronic pulmonary diseases, February 7.  
Dr. Francis G. Blake, New Haven, Conn., serum therapy, February 14.  
Dr. Frank H. Lahey, Boston, recent advances in surgery, February 27.  
Dr. Charles F. McKhann, Boston, diseases of children, March 7.

### OKLAHOMA

**Society News**—Dr. Morris Fishbein, Chicago, Editor of THE JOURNAL, will address the Pottawatomie County Medical Society, Shawnee, March 14.

**New Members of State Medical Board**—New members of the Oklahoma State Board of Medical Examiners are Drs. Samuel A. McKeel, Ada, Oscar C. Newman, Shattuck, George H. Stagner, Erick, and Samuel B. Leshe, Okmulgee. At a meeting February 3 Dr. McKeel was elected president. Dr. Calvin E. Bradley, Tulsa, vice president and Dr. James D. Osborn, Jr., Frederick, secretary.

### OREGON

**Society News**—A symposium on infection of the middle ear was presented before the Multnomah County Medical Society, Portland, February 1, by Drs. Frank B. Kistner, Ralph A. Fenton and Ralph I. Davis. Drs. Herbert V. H. Thatcher and Matthew C. Riddle addressed the society February 15 on 'Surgery of the Tendons of the Hand' and 'Recent Advances in Knowledge of Bleeding and Coagulation Problems' respectively. At a meeting of the Lane County Medical Society, Eugene, January 20 the speakers were Drs. Fred N. Miller and Marion G. Hayes, Eugene, on 'Streptococcal Pneumonia', Leshe S. Porter, Oregon City, 'Fractures of the Navicular Bone' and Ronald C. Romig, Eugene, 'Treatment of Carbuncle'.

## PENNSYLVANIA

**New State Health Officials**—Dr John J Shaw, Philadelphia, has been appointed state secretary of health to succeed Dr Edith McBride-Dexter. Dr Shaw is 55 years old and graduated from the University of Pennsylvania School of Medicine in 1908. Dr Alexander Hamilton Stewart, Indiana, has been appointed deputy secretary. He is 58 years old and graduated from the University of Pittsburgh School of Medicine in 1907.

## Philadelphia

**Society News**—Dr Foster Kennedy, New York, addressed the Northern Medical Association of Philadelphia February 20 on "The Organic Background of Mind." Dr Hyman I Goldstein, Camden, N. J., was recently elected president of the association. Dr Henry B. Kobler was recently elected president of the Medical Club of Philadelphia and Dr William S. Wray, secretary. Dr Robert A. Moore, New York, addressed the Pathological Society of Philadelphia, February 9, on "Benign Hypertrophy of the Prostate." Drs Abraham Trasoff and David R. Meranze presented a paper on "Mural Endocarditis Following Pulmonary Suppuration." At a meeting of the Philadelphia Pediatric Society February 14 the speakers included Drs Carl C. Fischer and Charles S. Raue on "Control of Contagion Without Formal Quarantine" and Mitchell I. Rubin, "Correlation of Blood and Bone Disturbances in Children."

## RHODE ISLAND

**Personal**—Dr Arthur H. Ruggles, Providence, recently received a silver plaque from the Men's Club of Temple Emanuel in recognition of his "outstanding achievement in the field of civic improvement, human betterment and the advancement of American ideals." Dr Ruggles has been superintendent of Butler Hospital since 1920. He is a former president of the New England Society of Psychiatry and of the National Committee for Mental Hygiene.

**Society News**—Dr Gordon M. Morrison, Boston, addressed the Providence Medical Association February 6 on "Therapeutic Applications of Occupational Therapy." The society has initiated a study of tuberculosis and has developed a long range plan for control of the disease. New legislation is being prepared for introduction in the state assembly relative to reporting of tuberculosis and isolation of positive cases. Dr Alexander M. Burgess, former president of the association, is chairman of a committee to study voluntary health insurance plans.

## TEXAS

**New Foundation for Medical Research**—The Southwest Medical Foundation is to be established under a charter granted by the state January 21 as a nonprofit corporation with no capital stock. The incorporators were Drs Edward H. Cary and Hall Shannon, Mr E. R. Brown and Mr Karl Hobltzelle, all of Dallas. The charter provides for a maximum of fifteen trustees, nine have been named. Besides those named as incorporators the trustees include Herbert Marcus and Rhodes S. Baker, Dallas, Jesse H. Jones and R. C. Fulbright, Houston, and Thomas O. Walton, LL.D., president of Agricultural and Mechanical College of Texas, College Station. The aims of the foundation are, according to a newspaper report, to establish facilities and clinics for the study of the causes, the prevention and the cure of diseases of the minds and bodies of needy persons residing in the Southwestern section of the United States and elsewhere, and to develop and train laboratory workers, physicians and nurses in the treatment of diseased persons, to study individual and community hygiene and to promote public health and medical research. An endowment will be sought, it was said, but the amount has not been determined. The foundation will be nonsectarian and noninstitutional, seeking to spread its benefits where they are most needed. It will finance work at Baylor University, Dallas, as well as elsewhere in the Southwest. Dr Cary has been elected president, Mr Brown and Mr Hobltzelle, vice presidents, Dr Shannon, secretary, and Mr Marcus, treasurer.

## WASHINGTON

**Annual Surgical Meeting**—Dr Kellogg Speed, Chicago, was the guest speaker at the annual dinner and clinic of the Seattle Surgical Society, January 20-21. Clinics were held both days at the King County Hospital (Harborview). Dr Speed also spoke at a dinner January 20 on "Fractures In and Around the Elbow" and at the annual banquet January 21 on "Everyday Injuries of the Knee Joint."

## GENERAL

**Meeting of American College of Physicians**—The twenty-third annual session of the American College of Physicians will be held in New Orleans March 27-31. Lectures, dry clinics at the Municipal Auditorium, special clinics, demonstrations and ward walks at several hospitals and round table conferences will make up the morning programs. General sessions will be held afternoons and evenings. Among the addresses at the general sessions will be:

- Dr Irvin Abell, Louisville, Ky. President of the American Medical Association. Some Professional and Social Trends in American Medicine.
- Drs Jacob C. Geiger, Jacques P. Gray and Albert E. Larsen, San Francisco. The Limitations of Government in Medicine: the San Francisco Experience.
- Drs Alexander E. Brown, Wallace E. Herrell and J. Arnold Barger, Rochester, Minn. Neoprontosil (Oral) in the Treatment of Chronic Ulcerative Colitis.
- Dr Perrin H. Long and Eleanor A. Bliss, Se D, Baltimore. Experimental and Clinical Use of Pyridine Derivatives of Sulfanilamide in the Treatment of Bacterial Infections.
- Howard B. Lewis, Ph.D., Ann Arbor, Mich. Vitamins in Theory and Practice.
- Conrad A. Elvehjem, Ph.D., Madison, Wis. The Nutritional Significance of Nicotinic Acid.
- Dr Tom Douglas Spies, Cincinnati. Recent Advances in the Treatment of Pellagra.
- Dr James P. Leake, U. S. Public Health Service, Washington, D. C. Human and Equine Encephalitis.
- Dr Maxwell Finland, Boston. Specific Serotherapy and Chemotherapy of Pneumococcus Pneumonias.
- Dr Stanley P. Reimann, Philadelphia. Chemical Specificity in Growth and Development.
- Drs Salomon Katzenelbogen, Baltimore, Alexander Simon, Anna R. Coyne and Charles C. Vigue, St. Elizabeths Hospital, Washington, D. C. Pharmacologic Treatment in Schizophrenic Patients.

At the annual convocation Wednesday evening Ernest O. Lawrence, Ph.D., professor of physics and director of the radiation laboratory, University of California, Berkeley, will give the annual address on "The Newer Physics and Medicine." The John Phillips Memorial Medal will be awarded and Dr William J. Kerr, San Francisco, will make his presidential address. The annual banquet will be Thursday evening, with Dr John H. Musser, New Orleans, as toastmaster. Addresses will be made by Mrs E. M. Gilmer (Dorothy Dix) on "A Heart Specialist Diagnoses Love Troubles" and Mr Lyle Saxon, "Strange Stories of Old New Orleans."

## PUERTO RICO

**Cattle Freed from Tuberculosis**—Puerto Rico and the Virgin Islands have been officially designated as modified accredited areas free from bovine tuberculosis, the U. S. Department of Agriculture announces. Tuberculin testing covered seventy-seven municipalities of the island, containing more than a quarter of a million cattle. In the Virgin Islands there were 12,000 cattle and not a single reactor to the test was found, the announcement said.

## FOREIGN

**Gift of Journals**—The American Hellenic Educational and Progressive Association has recently provided funds for subscriptions to *THE JOURNAL* and the *Journal of Pharmacology and Experimental Therapeutics* as a gift to the library of the University of Athens, Greece. It is reported that foreign exchange laws in Greece have made it difficult or impossible for physicians there to obtain foreign medical periodicals.

**Neurological Congress in Copenhagen**—Neurologists, psychiatrists and others interested in the nervous system may present papers before the third International Neurological Congress to be held in Copenhagen, Denmark, August 21-25. To secure a place on the program, a title and abstract must be submitted before April 1. Information may be obtained from the secretary of the committee for the United States, Dr Henry Alsop Riley, 117 East Seventy-Second Street, New York.

**Medical Meetings in Germany**—Announcement is made of various medical meetings to be held in Germany within coming months, as follows:

- German Society of Internal Medicine, Wiesbaden, March 27-30.
- German Society of Surgeons, Berlin, April 12-15.
- Third International Congress of Sanatoriums and Private Hospitals, Baden-Baden, April 23-28.
- Society of German Nose, Throat and Ear Specialists, Vienna, May 25-27.
- German Association of Microbiologists, Vienna, March 27-30.
- International Society of Orthopedics and Traumatology, September 4-8.
- and German Orthopedic Society, September 8-9, both in Berlin.

## CORRECTION

**The Treatment of Infantile Eczema**—Prescription 2 and Prescription 6 in Sulzberger's article on "The Treatment of Infantile Eczema" in *THE JOURNAL*, January 7, beginning on page 38, will be clarified by substituting in them in the last lines "equal parts of each in sufficient quantity to make" in place of the words as published "each in sufficient quantity to make."

#### Contributory Schemes for Hospitals

Not long ago all the hospitals were described as 'voluntary' because they were supported by voluntary contributions for the service of the poor, who received free treatment, but in recent years the system of patients' making contributions has been introduced. Speaking at the British Hospital Schemes Association, Lord Horder said that there were at least 400 such schemes in the country, which raise annually more than \$17,500,000. The rates of contribution varied from 2 to 8 cents a week. It was estimated that contributory schemes provided about one third of the annual income of all voluntary hospitals in the provinces. They ranged from the Hospital Saving Association of London with a membership of nearly 2,000,000, to associations in rural communities around small cottage hospitals, with memberships as small as 1,000. In return for his weekly payment the wage earner obtained immunity from investigation into his financial circumstances and immunity from any charge when admitted to a hospital. In most cases he and his dependents also got a variety of auxiliary services free—convalescent home, ambulance, transport and home nursing. The aim should be full cost of maintenance. Whether any payment should be made to the physician out of contributory funds was a moot point. The logic of the position demanded that it should, but the physicians' claims were at present waived. The generosity of the profession, however, should not be too long abused. In recent years the municipal hospitals, which are supported by the local authorities, have greatly developed, so that they now supply a service comparable to that of the voluntary hospitals. Lord Horder thought that the maintenance of the two on parallel lines was wasteful, collaboration between them should be organized regionally.

#### Anorexia Nervosa

Anorexia nervosa is a rare disease which was described first by the celebrated English physician Sir William Gull in the last century. Whether because of increased incidence or because of wider recognition it has recently received increased attention in this country. On the other hand it does not appear to be well understood in other countries, in which it is often confounded with the still rarer Simmonds's disease. At a discussion on anorexia nervosa at the Royal Society of Medicine Prof. J. A. Ryle opened with a paper based on sixty-three private patients, of whom 90 per cent were females, most of them girls and unmarried women under 30. The majority were psychoneurotic and some were psychotic. The etiologic factors included emotional disturbance, overwork and slimming in response to teasing. A perpetuating factor was morbid enjoyment of the illness or of the interest it created. The clinical picture included the effects of starvation with amenorrhea, slow pulse, low blood pressure and hirsuties. The loss of weight might be extreme: in one case the reduction was to 4 stone (25 Kg). The prognosis was good provided diagnosis was not unduly delayed. The treatment was rest in bed, a full diet and removal from the parental sphere.

Dr. J. H. Sheldon said that in American and German literature cases were misreported under the heading Simmonds's disease. That disease, starvation and anorexia nervosa had clinical features in common. Anorexia nervosa arose in response to an emotional or mental need. The lowered food intake set in motion a series of changes which were mediated by diminished pituitary activity, hence the acceptance of cases

abroad as instances of Simmonds's disease. The early onset of the amenorrhea in some cases pointed to diminished pituitary output.

Dr. A. W. Spence said that the initial disturbance was psychologic and that endocrine disturbance was purely secondary. This differentiated the condition from Simmonds's disease. Glandular therapy was disappointing. It was remarkable that the more severe nutritional disorders, such as scurvy or beriberi, never occurred.

Sir Arthur Hurst said that anorexia nervosa had nothing to do with Simmonds's disease. All the symptoms were due to purely psychologic causes or to starvation. It was important that the distinction should be understood, because since the question of Simmonds's disease arose the patients had been worse treated. They need not worry about vitamins or endocrine preparations. What was required was encouragement to eat ordinary food. If the patients were treated by modern psychologic methods they did badly.

### PARIS

(From Our Regular Correspondent)

Feb 4, 1939

#### Pulmonary Tomography

The value of pulmonary tomography, as based on their personal observation of 200 cases, was the subject of a paper read at the Nov. 4, 1938, meeting of the Societe medicale des hopitaux of Paris by Dr. Leon-Kindberg and his co-workers. The underlying principle of tomography, i. e. examination in section, is to eliminate shadows due to the ribs, clavicle and sternum in the X-ray examination of the lungs, so that a single area can be studied in detail. The 200 examinations included 155 on patients with pulmonary tuberculosis and forty-five on patients with cancer, pulmonary abscess, cysts and bronchiectasis.

This recent method has the following advantages: 1. It gives details as to the topography of lesions. 2. It yields information as to obscure or complex foci. 3. It shows some lesions which escape detection by other methods. 4. It permits study of the structure and evolution of lesions. The method has been sufficiently perfected so that no failures were noted in more than 2,000 films. A pitfall observed by others in the form of "false cavities," i. e. defects diagnosed as such but in reality due to faulty interpretation of the films, was not encountered by the authors. As to added expense, this cannot be an objection, because the stratigraphic (tomographic) method permits earlier diagnoses to be made. It has almost completely supplanted the older methods in the service of Dr. Leon-Kindberg at the Hopital Beaujon in Paris. A number of slides illustrating the advantages of tomography were shown.

#### Treatment of Spastic Colitis

The contributions of Prof. Rene Leriche and his associates to the surgery of the sympathetic nervous system are familiar to every one interested in neurosurgery. In the January 7 *Progress medical* Professor Leriche and his two associates Drs. Kunlin and Froehlich report their experience in the treatment of certain forms of spastic colitis by infiltration of the lumbar sympathetic and section of the splanchnic nerve. Nine patients who presented the typical clinical syndrome of chronic spastic colitis were treated in this manner. The diagnosis was based on the occurrence of pain, constipation, emaciation, depression and the roentgenographic finding of either (a) intense spasm of the transverse and descending colon or of the latter alone, with or without associated diverticulosis, or (b) an atonic deformity with massive thickening of the wall of the descending colon. Usually the pain ceases after the first injection, and after a second one the constipation is alleviated to such an extent that there is a daily evacuation without laxatives.

In a few cases a persisting pain on the right side has necessitated an infiltration of the corresponding lumbar sympathetic. In one patient, who was reexamined eighteen months after three infiltrations had been given, the symptoms had entirely disappeared but the x-ray evidence remained the same. The infiltration appeared to have modified the functional element, which is neurogenic, without having any influence on the anatomic changes. The authors were unable to give any physiologic explanation of their results, because the physiology of the colon is very complex.

Four patients are cited who were treated by infiltration of the lumbar sympathetic and one in whom a splanchnic resection was done. In a woman aged 21 the indication for operative intervention was intractable chronic constipation. The left splanchnic nerve and first lumbar ganglion were resected. Daily movements without any laxatives began on the seventh day after operation. There was a rapid gain in weight, with an improvement in the general condition which has continued during the sixteen months since the operation. The authors call attention to the careful study of every case of constipation due to spastic colitis since not all patients can be benefited by infiltration of the lumbar sympathetic or resection of the splanchnic nerve.

Jan 23, 1939

#### New Regulation of Midwives

The German national government, Dec 21, 1938, announced a new "statute of midwives," in which it is stipulated that every woman in the German reich is entitled to the services of a midwife. These services are construed to include advice and assistance during pregnancy, supervision and attendance at births and miscarriages and, in addition, care of lying-in women and newborn babies. A midwife must at any time be prepared on request to attend gravidas, parturients, puerperants and newborn infants, regardless of the patient's social and economic status. Every pregnant woman must engage a midwife in good season to attend her during confinement. If for any reason this has been impossible, the mother must immediately after parturition call in a midwife to care for herself and the baby. It is the duty of every physician to see to it that a midwife assists at every confinement within his practice. If the doctor finds that it has been impossible to have a midwife present at the birth, he must see to it that a midwife is immediately obtained to care for the lying-in woman. Accordingly, in the future a birth which a midwife does not attend will be possible only in exceptional circumstances. For obstetric services (namely supervision from the onset of labor pains and assistance during labor), with the exception of physicians, only those persons who have passed a proper examination and been duly granted the so called residence license are officially recognized as competent practitioners of midwifery in a particular community. Local authorities may fix an age limit beyond which no midwife may remain in practice. The mentioned residence license is designed to effect an equitable national distribution of midwives on the basis of density of population and transportation facilities. Therefore when a midwife receives her residence license she is officially assigned to a certain place of domicile (Jewesses are, needless to say, ineligible for the residence license). Licensed midwives are guaranteed a certain minimal annual income. If a midwife's income falls below the minimum, the difference is paid her by the government. Conversely, the midwife who attends a number of women in excess of a certain quota allotted by the guarantors of her income must turn over a part of her earnings to the proper authorities. The fees to be asked by midwives may be fixed by local regulation. Since the statute fails to stipulate the exact amount of the guaranteed income, this may

differ in various parts of the country. Special measures for the benefit of superannuated midwives are included in the law.

The new statute represents the first uniform, nationwide piece of legislation in this field. Some such measure was all the more necessary in view of the fact that conditions with regard to midwifery have been quite dissimilar in various provinces of Germany and in some places actually unsatisfactory (because of excessive numbers of midwives, superannuation and unequal geographic distribution). Then too, under the new law a mother has the right to be attended by the midwife of her choosing and hence is not compelled to engage a certain person. In addition the midwife has the right to practice beyond the boundaries of her assigned district of residence if she is called on to do so.

#### Prophylaxis of Goiter in Austria

The psychiatrist and authority on goiter Prof. Julius Wagner-Jauregg has recently published a short monograph on the important problem of goiter, long a concern of Austrian scientists. To the article is appended a truly formidable body of statistical data on the incidence of goiter. During the school year 1923-1924, pursuant to an order of the federal health bureau, 686,000 school children, an overwhelming majority of all Austrian school children, were examined for goiter by the school physicians. In order to assure the greatest possible standardization of the examinations, special, carefully prepared forms equipped with illustrations were utilized, patterned after the blanks used by the Swiss worker Bayard. Four stages were differentiated: (1) no goiter, (2) incipient goiter, (3) manifest slight enlargement of the thyroid and (4) prominent well developed goiter.

Gross observations of the survey are shown in the accompanying table. In smaller areas higher rates and lower rates, respectively, were observed.

#### Statistics on Goiter in Austrian Children, 1923-1924

Boys	55.8 per cent	nongoitrous	44.2 per cent	goitrous
Girls	51.8 per cent	nongoitrous	48.1 per cent	goitrous
Morbidity of Goiter				
				%
Lowest regional rate (Burgenland province)				Boys 15.9
				Girls 19.5
Highest regional rate (Vorarlberg province)				Boys 58.9
				Girls 63.6
Vienna				Boys 41.1
				Girls 46.2

The data considered as a whole evidence the high incidence of goiter among the school children of Austria in 1923-1924 but Wagner-Jauregg now believes that these high figures were conditioned by an ephemeral goiter wave which attained its peak in the mentioned year. At that time prophylaxis by the use of iodized salt and iodine tablets was instituted in Austrian schools (although not thoroughly carried out, to be sure). In subsequent years it would have been extremely interesting to compare this survey with other equally extensive surveys in order to study the effectiveness of goiter prophylaxis, but unfortunately this was impossible for financial reasons.

### Marriages

JOSEPH FREDERICK MCCLUGHAN, Newburgh, N. Y., to Miss Annette Manderson Stahl of Haverford, Pa., Nov. 24, 1938.

VALDEMAR CHRONOVSKY, Pendleton, Ore., to Miss Genevieve Renfrow of Wallowa, at Cathlamet, Wash., Oct. 26, 1938.

JAMES W. DOUGHTY, Sedro Woolley, Wash., to Mrs. Ina Rothausen of Seattle, Nov. 2, 1938.

JOHN S. GOLDCAMP, Philadelphia, to Miss Elizabeth C. Hart of Bethlehem, Pa., February 4.

ADAM J. EARNLEY to Miss Ruth Klopp, both of Millersburg, Ohio, Dec. 11, 1938.

## Deaths

**Walter Louis Horn** • New York, Fordham University School of Medicine, New York, 1916, member of the American Academy of Ophthalmology and Oto Laryngology, fellow of the American College of Surgeons on the staffs of the Mount Sinai Hospital, Misericordia Hospital and Manhattan Eye Ear and Throat Hospital honorary police department surgeon, aged 47, died, Dec 29, 1938, of hypertension

**Cyrus Knapp Merriam**, Spokane, Wash. University of the City of New York Medical Department, 1879, from 1880 to 1887 served as medical officer at various army posts of the northwest, member and past president of the Washington State Medical Association formerly secretary of the Spokane County Medical Society, aged 90, died Dec 6 1938, of myocarditis, chronic bronchiectasis and chronic nephritis

**Arthur John McLean**, Portland, Ore. Johns Hopkins University School of Medicine, Baltimore, 1925, fellow of the American College of Surgeons, assistant professor of pathology at the University of Oregon Medical School on the staffs of the Multnomah County Hospital, Good Samaritan Hospital and the Emanuel Hospital, aged 44, was killed Dec 7, 1938, in an automobile accident

**John Emmet Early**, Charlottesville, Va. University of Virginia Department of Medicine Charlottesville, 1893, member of the Medical Society of Virginia formerly member of the city council and city school board aged 71, died Dec 12, 1938, in the Martha Jefferson Hospital of carcinoma of the liver

**John Whitlock Hairgrove**, Salem Ore. Missouri Medical College, St Louis, 1885 fellow of the American College of Surgeons, served for many years on the staffs of the Passavant Memorial Hospital and Our Saviours Hospital, Jacksonville, Ill., aged 82, died Dec 21, 1938, of cerebral hemorrhage

**John Hicks Florence**, Houston Texas, Louisville (Ky.) Medical College, 1889, member of the State Medical Association of Texas, at one time state health officer and city health officer of Dallas formerly member of the state legislature, aged 70 died, Dec 28 1938 of coronary occlusion

**Samuel Holedger Eckles**, Tucson, Ariz., Medico Chirurgical College of Philadelphia, 1913, member of the Arizona State Medical Association served during the World War, aged 58, died Dec 3, 1938 of heart disease, bronchial asthma and acute dilatation of the stomach

**David Robert Lloyd**, Brooklyn University and Bellevue Hospital Medical College New York, 1901 formerly on the staffs of the Brooklyn and Greenpoint hospitals and the House of St Giles the Cripple, aged 67, died suddenly, Dec 25, 1938, of coronary thrombosis

**Charles Odell Petty**, Fullerton, Calif., Gross Medical College, Denver, 1900 member of the California Medical Association, on the staff of the Fullerton Hospital aged 66, died, Nov 17, 1938, of coronary sclerosis with rupture of the heart muscle

**Elmer Williams Weirich**, Angels Camp Calif., Hahnemann Hospital College of San Francisco 1889, member of the California Medical Association, aged 72 died, Nov 20 1938, of arteriosclerotic heart disease and generalized arteriosclerosis

**Marvin Hall** • Topeka, Kan., University of Louisville (Ky.) Medical Department, 1917 served during the World War on the staffs of the Christ Hospital and St Francis Hospital, aged 45, died, Dec 21, 1938, of lymphatic leukemia

**Jesse Wright Eads**, Camp Wood, Texas Fort Worth School of Medicine Medical Department of Fort Worth University 1900, member of the State Medical Association of Texas aged 76 died, Dec 10, 1938, of cancer of the prostate

**Peter Arthur Tobin**, San Francisco Medical Department of the University of Cincinnati 1912, member of the California Medical Association, aged 51 died, Nov 21 1938 of cholelithiasis bronchopneumonia and postoperative peritonitis

**Thomas G Cunningham** Atlanta Ga., Atlanta College of Physicians and Surgeons 1899 aged 66 died Dec 11, 1938 at his home in Decatur of pulmonary tuberculosis bronchial asthma, pleurisy, arteriosclerosis and gallbladder disease

**Jesse Alpha MacDonald**, Collinsville Miss. Tulane University of Louisiana School of Medicine New Orleans 1934 formerly connected with the county health department, aged 28 died, Dec 2, 1938 of a self-inflicted bullet wound

**Louis Milton Mitchell**, Batesburg S. C., University of Maryland School of Medicine Baltimore 1892, member of the

South Carolina Medical Association, aged 80, died, Dec 10, 1938, in the Leesville (S. C.) Infirmary of pneumonia

**Lee Roy Farmer**, Alliance, Neb., National University of Arts and Sciences Medical Department, St. Louis, 1916 served during the World War, city physician, aged 45, died, Dec 20, 1938, of coronary thrombosis and chronic nephritis

**Edwin B. Hatler**, Carlisle, Ky., University of Louisville School of Medicine, 1930, member of the Kentucky State Medical Association, aged 39, died, Dec 23 1938 in the Good Samaritan Hospital, Lexington, of septic kidney

**Arthur Byron Egan**, Muskegon, Mich., Michigan College of Medicine and Surgery, Detroit, 1906, member of the Michigan State Medical Society, served during the World War, aged 55, died, Dec 16, 1938, of cirrhosis of the liver

**Nathaniel Ferdinand Yates**, Cherry Valley, N. Y., Long Island College Hospital Brooklyn, 1892, for many years health officer aged 80, died, Nov 20, 1938, of infection of the genito-urinary tract due to cancer of the prostate

**James D. Middlebrooks**, Powder Springs, Ga. Atlanta Medical College 1882 member of the Medical Association of Georgia, aged 77, died Dec 2, 1938, of arterial hypertension, arteriosclerosis and cerebral hemorrhage

**John Henry Cristler**, Dallas, Texas. Rush Medical College, Chicago, 1873, aged 91, died Dec 10, 1938, in the Baylor Hospital of thrombosis of the left femoral artery, amputation of the left leg and cardiac decompensation

**Henry Powell Rush** • Corpus Christi, Texas, Fort Worth School of Medicine, Medical Department of Texas Christian University, 1905 served during the World War, aged 55, died, Nov 11 1938, of heart disease

**Raymond Alanson Miller** • Newburgh N. Y. University and Bellevue Hospital Medical College, New York, 1911, on the staff of St. Luke's Hospital, aged 61 died, Nov 30, 1938, of coronary occlusion

**Howard Franklin Hoffmeier**, Mauch Chunk, Pa., Medico-Chirurgical College of Philadelphia, 1903, was a member of the board of health aged 63, was found dead, Nov 30, 1938, of coronary thrombosis

**Frank P. Harvey**, Chicago, Bennett College of Eclectic Medicine and Surgery, Chicago, 1900, aged 59, died, Dec 7, 1938, in the Swedish Covenant Hospital of hypertension and arteriosclerosis

**Edward M. Cates**, Wayne City, Ill., Barnes Medical College St. Louis, 1903, member of the Illinois State Medical Society, also a pharmacist, aged 69, died Dec 14 1938, of pneumonia

**Edwin Lethridge Myrick** • Fort Worth, Texas University of Nashville (Tenn.) Medical Department 1897, served during the World War, aged 63, died, Nov 7, 1938, of coronary occlusion

**Byron W. Walling**, Poolesville, Md., College of Physicians and Surgeons, Baltimore, 1875, for several years mayor, aged 86, died, Nov 14, 1938, of cerebral hemorrhage and arteriosclerosis

**Ellsworth E. McPeck**, Rochester Minn., College of Physicians and Surgeons Keokuk, Iowa, 1892, aged 68, died, Nov 18, 1938, of arteriosclerosis with rupture of the aorta and hemorrhage

**Otto M. Reinhardt**, Baltimore, Baltimore University School of Medicine, 1893, coroner of the Southern district for many years, aged 67 died, Nov 19, 1938, of carcinoma of the cervical gland

**Claude Eugene Frazier**, Kansas City, Mo., Eclectic Medical University Kansas City, Mo., 1904, served during the World War, aged 62, died, Dec 1, 1938, of diabetes mellitus

**William Sullivan Howell**, Winnebago Ill., Keokuk (Iowa) Medical College, 1898 aged 63 died, Dec 16, 1938 in the Mercy Hospital, Chicago, of prostatic hypertrophy and urosepsis

**Samuel Everett Gaston**, Meta, Mo. Kansas City Hahnemann Medical College, Kansas City 1910 served during the World War, aged 50, died, Dec 2, 1938, of arteriosclerosis

**George Eugene Kleeman**, Oakland, Calif. College of Physicians and Surgeons, San Francisco 1904 aged 61, died, Nov 17 1938 of arteriosclerosis and coronary disease

**Charles W. Klinetop**, Chicago, Hering Medical College, Chicago 1894, aged 74, died, Nov 8, 1938 in Rancho Los Amigos Calif., of myocarditis and arteriosclerosis

**Luke Melvin Holmes**, Boston College of Physicians and Surgeons, Boston, 1903 died, Nov 18, 1938

**Virgil H. Hendricks**, Jasper Mo., Barnes Medical College, St. Louis, 1897, aged 66, died, Nov 9, 1938

## Correspondence

### INFORMATION, PLEASE, ABOUT DOCTORS WHO ARE LAWYERS OR VICE VERSA

*To the Editor*—I am being impressed with the number of professional men who hold degrees as Doctors of Medicine and who also have received degrees from accredited law schools and are admitted to practice before the several courts of their states and country.

An effort is being made to secure and list all persons who possess the rights to practice medicine and law and who hold unrevoked licenses to engage in these two professional activities. The information is not obtainable from medical or law directories.

An appeal is therefore being made that persons holding the rights to practice medicine and law send their name, address and data pertaining to their education in medicine and law to the undersigned. It will be appreciated also if a statement is included as to whether full time is devoted either to law or to medicine or whether the person engages in the practice of both professions.

FRANK C. WARSHUIS, M.D.,  
137 Newbury Street, Boston

President and Editor in Chief, American  
Medico Legal Association

### AMMONIATED MERCURY IN IMPETIGO

*To the Editor*—In *THE JOURNAL* January 21, page 261, appears a letter from Dr. J. G. Downing of Boston with a note of warning against the use of ammoniated mercury in the treatment of impetigo in the newborn and of its possible effect of causing diarrhea. Without attempting to discuss the latter factor, I should like to suggest the use of a 1 or 2 per cent alcoholic solution of gentian violet in the treatment of impetigo. Some fifteen years ago it occurred to my associates and me that any gram positive organism should be killed by the use of gentian violet. It was also found that the *Sacharomyces albicans* causing thrush was gram positive. For use in the mouth we employed a 1 or 2 per cent aqueous solution of gentian violet. Since adopting these procedures we have had practically no difficulty in curing either thrush or impetigo with reasonable promptness. In fact, thrush will disappear within twenty-four hours. Several years later Dr. Faber wrote an article on the local use of gentian violet but apparently its efficacy has not been generally recognized.

JOHN C. GITTINGS, M.D., Philadelphia

### CHANGES IN CELLS AFTER FRACTIONAL DOSES OF X-RAYS

*To the Editor*—In a recent article in *THE JOURNAL* (Schmitz, Henry, Schmitz, H. E., and Sheehan, J. F. The Action of Measured Doses of Eight Hundred Kilovolt Roentgen Rays, January 7, p. 17) the authors describe, among other changes, the finding of large numbers of degenerating giant tumor cells in squamous cell carcinoma of the uterine cervix treated by fractional doses of x-rays. We reported this finding in tumors in experimental animals at the International Congress of Radiology in 1937 and in the *Archives of Pathology* (23:757 [June] 1937), and we are pleased that the same picture has now been observed in human cancer. One of us (P. J. M.) has also observed the phenomenon in several varieties of irradiated human cancer.

Although occasional giant tumor cells have been seen by a number of workers they develop in abundance only in the later stages of treatment by fractional methods of radiation. After

the radiosensitive tumor cells have been destroyed, the remaining resistant cells appear to become transformed into abnormal cell forms (giant cells), owing to a progressive interference with the mechanism of cell division, by a cumulative action of the fractional doses. This is a different process from simple hydropic swelling of the nuclei due to hydrogen ion changes.

PERRY J. MELNICK, M.D., PH.D.  
ALBERT BACHENI, PH.D.

## Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

### AMPHETAMINE (BENZEDRINE) SULFATE FOR ALCOHOLISM

*To the Editor*—The use of the drug benzedrine to cure habitual drunkenness is recommended by Dr. Wilfred Bloomberg of Harvard University. Is it safe? He uses it in pill form. What is the dose? Where obtained?

E. A. THOMPSON, M.D., Breckenridge, Mo.

ANSWER—Benzedrine to cure habitual drunkenness was mentioned in a news report concerning its use in place of liquor for cocktail parties. The final sentence of this press release stated: "Although many of the alcoholics experimented upon were cured, Dr. Bloomberg does not maintain that the treatment is a solution for all addicted to liquor."

The Council on Pharmacy and Chemistry within the last year has published a report, "The Present Status of Benzedrine Sulfate," which has a considerable number of warnings concerning the use of this preparation by the general public, and its use for the purpose of "pepping up" or of getting a "kick" out of its effects is most definitely decried.

There are several other features which Dr. Bloomberg has apparently overlooked, among them the fact that, while alcohol is a dilator of blood vessels, benzedrine is a vasoconstrictor. The difference in effect, for example, of alcohol and benzedrine in potential coronary disease requires serious consideration.

The release of information of this type to the daily papers is always considered objectionable. There have been many releases on the use of benzedrine sulfate by the layman without resort to a physician's prescription. In accepting benzedrine sulfate the Council was careful to point out that no such uses should be made of the drug, and such a stipulation applies most definitely to the recent release on Bloomberg's work.

Since the advent of the press release, Dr. Bloomberg's article has appeared (Wilfred Bloomberg, Treatment of Chronic Alcoholism with Amphetamine [Benzedrine] Sulfate, *New England J. Med.* 4:129 [Jan. 26] 1939) and he states, "It would be oversanguine to assume that amphetamine sulfate can alone solve the problem of alcoholism. In almost all the cases in this series, the patients have gone through a more or less prolonged period of greater accessibility, due to their sobriety. If one assumes that the patients in this group who have been most successful represent those who were really anxious to stop drinking but had been unable to do so without external assistance, the improved rapport between patient and psychiatrist is understandable, when the patients find that they have actually been able to stop drinking. The fact that this has been accomplished without hospitalization is also quite important. Because of the experimental aspect of this study, no attempt has been made to take advantage of the situation. However, it is my belief that the greatest benefit from the use of amphetamine sulfate in alcoholics will arise out of this circumstance. The free interval which amphetamine sulfate appears able to produce should allow time for the institution of more fundamental psychotherapeutic approaches. Probably the real value of the treatment will prove to be just this opportunity to inaugurate psychotherapy on a basis of good rapport and confidence and sobriety, so that the gain made by the treatment may be consolidated by more fundamental modifications of the alcoholic's personality and his attitude toward life."

### SPLENIC EXTRACT IN ALLERGIC DISORDERS

To the Editor—Can you advise me regarding the present status of splenic extract in the treatment of asthma?

J C KERN MD Sanderson Texas

To the Editor—Would you kindly advise me of the status of splenic extract in allergy and acne

W F CANTWELL MD International Falls Minn

ANSWER—A number of articles have been written in which splenic extract was said to have virtue in combating allergic states such as hay fever, vasomotor rhinitis and various allergic skin conditions including eczema and urticaria. Theoretically the use of splenic extracts in the treatment of allergic conditions is based on the usual reduction of the number of eosinophils when splenic extract is injected in an allergic individual. There is a large foreign literature on the effectiveness of splenic extracts, but most observers seem to feel that any action which this method of treatment may have is a nonspecific one.

If splenic extract has been proposed for the treatment of acne, it has received no corroboration and certainly no general acceptance among dermatologists. Its use, therefore, must be considered experimental at the present time, not only for this condition but probably for all others for which it has been proposed. The Council on Pharmacy and Chemistry has not accepted it for inclusion in New and Nonofficial Remedies.

### CHROMOSOMES SEX DETERMINATION AND TWINNING

To the Editor—What factor determines sex in the human embryo? I have always thought that the forty seventh (odd) number of chromosomes in the male germ cell in the process of maturation determined sex. What factor determines the single or multiple births at one lying in? This I have always believed was determined by the female. Something I read recently seemed to hold that the paternal element could influence this matter.

MAUD PARKER MD Richmond Highland Wash

ANSWER—The answer to this query must be broken into several parts.

1 There are forty-eight chromosomes in both male and female human beings. The female has two X-chromosomes of equal size, the male one X-chromosome and a small Y-chromosome.

2 Sex is determined at the time the egg is fertilized by the sperm, not during maturation.

3 The causes of twinning are not surely known. Two egg twinning seems to be slightly hereditary, equally through maternal and paternal lines. One-egg twinning seems to have no hereditary basis.

### OSTEOSCLEROSIS

To the Editor—Two years ago after the football season a 15 year old boy complained of pain in the leg. His school doctor treated him without relief. He then took x-ray films which showed a localized thickening of the tibial cortex. There was no history of bone injury. I operated to obtain a specimen and at the same time leveled off the bone. Since then unexplainable pain has not occurred. I had him in plaster for four weeks. The specimen was said to show simply a bone sclerosis. Now the school doctor reports a complaint of pain in the arm without relief from treatment. x-ray examination shows a similar condition to the tibia. What is this? He has had no fever at any time. MD, New Jersey.

ANSWER—This is evidently a case of localized osteosclerosis, probably of traumatic origin. Either one definite blow or several minimal injuries produced a periostitis or a hematoma which ossified. It may be a case of Garre's sclerosing osteomyelitis. The query does not say which arm bone was involved nor in what part of the bones the lesions occurred. Roentgenograms of other long bones, of the skull, of the ribs and of the pelvis should be taken. The two lesions may not be related. The boy might have had benign osteoma of the tibia but may have a more serious lesion in the other bones.

### CONJUNCTIVITIS FROM CONCRETE

To the Editor—A patient after working for four months at a concrete mixer developed a bilateral conjunctivitis which has cleared up leaving no visible scarring yet he complains of dimness of vision and the eye card reads only 20/80. I should like to know whether the condition could be caused from his illness and how.

MD Mississippi

ANSWER—From the account of the case there seems but little chance that the injury was responsible for the dimness of vision. A careful examination with the slit lamp and corneal microscope would be necessary to make certain that no scar was present, but it seems most probable that there was some visual defect present before the injury of which the patient became conscious only after his attention was called to it by the injury. It is quite possible that he has refractive error which requires attention.

## Council on Medical Education and Hospitals

### ADDITIONAL HOSPITALS APPROVED

The Council on Medical Education and Hospitals of the American Medical Association has given its approval to the following hospitals since the publication of the last previous list in THE JOURNAL, Dec 31, 1938

#### Hospitals Approved for Intern Training

Good Samaritan Hospital Phoenix Ariz  
St Francis Hospital, Wilmington Del  
Belmont Community Hospital Chicago  
Chelsea Memorial Hospital Chelsea Mass

## Book Notices

**Psychotherapy** By Paul Schilder, M.D. Ph.D. Clinical Director  
Bellevue Hospital Psychiatric Division New York Cloth Price \$3.50  
Pp 344 New York W W Norton & Company Inc 1938

Although the general medical literature is well filled with monographs on treatment, the therapeutic approach to mental disease has been neglected. Except for one publication by Diethelm, which does not stress psychologic treatment, no recent volume attempts to cover the subject. There are, of course, numerous publications dealing with hypnosis, psychoanalysis, progressive relaxation and other forms of therapeutics of mental diseases, but an all inclusive manual on psychotherapy has been lacking up to now. To make such a volume worth while the author needs to be equipped with a deep understanding of the subject based on wide personal experience and thorough training. He should not be pinned down to a narrow field of interest such as psychoanalysis alone but should be psychoanalytically trained, combining such training with a good knowledge of neurology, general psychiatry, hospital care and treatment of the insane and near insane. His experience should be derived from a sufficiently extensive practice so that he not only understands the theory of treating his patients but will have been able to see the results of his treatment. The present author fulfills these requirements of good authorship.

It might be felt that the present volume would be too deep or too detailed for the average psychiatrist, but Schilder has been able to write clearcut, easily understandable English. The first half deals with general principles, treating largely from a modified psychoanalytic standpoint the importance of various symptoms either as a source of satisfaction to the patient or as a source of annoyance to those about him. The significance of organic symptoms, or lack of symptoms, of the affective thinking process and the understanding of the patient are brought out in comprehensive and interesting chapters, and there is given to the therapist who is really anxious to practice his art an understanding of the meaning of symptoms on an easily interpretable basis.

The second half of the book deals with such large topics as the relation of the physician to his patients and of various technics which can be used. It concludes with a brief discussion of the therapeutic procedures to be brought to bear on specific mental disorders. Schilder has never been onesided in his use of the various forms of psychotherapy which are available and he not only discusses conventional psychoanalysis and the theories of Jung and Adler (he considers the former as being artistic and unscientific) but he gives valuable pointers to the properly trained psychiatrist who wishes to use hypnosis and abridged methods of psychoanalysis. One of the most interesting features of the chapters dealing with treatment is a discussion of what the author calls "group treatment" as distinct from the socializing group treatment of the usual state hospital or Burrow's phylo-analytic methods of group analysis. Extensive questionnaires and investigations are used, some of which would seem to be likely to get an inexperienced examiner into some difficulty with a squeamish patient who is wrapped up in his sexual problems or has a puritanical background, but the procedure itself is well worth consideration of the psychiatrist who neither can afford the time nor can provide himself with sufficiently wealthy patients to justify lengthy "real" psychoanalysis.

The final chapter, considering treatment of specific syndromes, is too short. For its common sense point of view, scientific honesty, careful, systematic and useful compilation of technics, this book is unique.

**The Troubled Mind A Study of Nervous and Mental Illnesses** By C S Bluemel M.A. M.D. F.A.C.P. Cloth Price \$3.50 Pp 220  
Baltimore Williams & Wilkins Company 1938

This book consists largely of a textbook-like monograph on neuroses and psychoneuroses. It is different from the usual directive work for psychiatrists in that out of eight parts in the volume only one is devoted to the psychoses. It is not a particularly great contribution to the subject of study and treatment of the psychoneuroses for it neglects dynamisms and deep interpretations, consisting largely of brief, not particularly

## Medical Examinations and Licensure

### COMING EXAMINATIONS

#### STATE AND TERRITORIAL BOARDS

Examinations of state and territorial boards were published in THE JOURNAL March 4 page 873

#### NATIONAL BOARD OF MEDICAL EXAMINERS

NATIONAL BOARD OF MEDICAL EXAMINERS Parts I and II Medical centers having five or more candidates desiring to take the examination May 12 (Part II only—limited to a few centers) June 1921 and Sept 11 13 Ex Sec Mr Everett S Elwood 225 S 15th Street Philadelphia

#### SPECIAL BOARDS

### Arkansas November Examination

Dr L J Kosminsky, secretary, State Medical Board of the Arkansas Medical Society, reports the written examination held at Little Rock, Nov 3-4, 1938. One candidate was examined and passed. The following school was represented:

School	PASSED	Year Grad	Per Cent
University of Minnesota Medical School		(1933)	91.5

Twenty-two physicians were licensed by reciprocity from June 7 through December 19. The following schools were represented:

School	LICENSED BY RECIPROCITY	Year Grad	Reciprocity with
University of Arkansas School of Medicine		(1937)	Illinois
University of Colorado School of Medicine	(1932)	(1936)	Colorado
Chicago Medical School		(1935)	Illinois
Tulane University of Louisiana School of Medicine		(1935)	Missouri
(1937) (1938) Louisiana			
Johns Hopkins University School of Medicine		(1928)	Maryland
St Louis University School of Medicine		(1937)	Missouri
John A Creighton Medical College		(1906)	Nebraska
University of Oklahoma School of Medicine		(1937)	Oklahoma
Jefferson Medical College of Philadelphia		(1932)	New Jersey
(1936) New York			
Medical College of the State of South Carolina		(1914)	S Carolina
Meharry Medical College	(1933)	(1937)	Tennessee
Memphis Hospital Medical College		(1898)	Louisiana
University of Tennessee College of Medicine		(1937)	Tennessee
Vanderbilt University School of Medicine	(1924)	(1935)	Tennessee
University of Texas School of Medicine		(1935)	Texas
Medical College of Virginia		(1931)	Virginia

thoroughgoing, case studies Each chapter is packed with a number of these short summaries The case histories contain much discussion and exemplification of symptomatic materials and patients' reports of their introspections and their attitudes Many psychiatrists will disagree strongly with the diagnosis given for these cases on a basis of the symptoms listed under each diagnostic category The mechanisms involved in the various types of neuroses are not gone into to any great extent, nor is the discussion of therapy modern or extensive Much of the terminology is old fashioned and certain of the concepts, such as the use of the concept of inhibition of dealing with certain psychoneuroses, such as hysterical paralysis, are of doubtful psychiatric significance The book does not follow modern conventional psychiatric lines to any great extent It offers no contribution to the study and treatment of the psychoneuroses, and because of the fact that it is so unconventional and adheres so much to the older concepts it is of doubtful value for teaching purposes

*Tuberculose et médecine sociale* Par Etienne Bernard professeur agrégé à la Faculté de médecine de Paris Préface de F Bezançon Paper Price 36 francs Pp 159 with 4 illustrations Paris Masson & Cie 1938

This is a complete discussion of the tuberculosis problem in France It contains an unusually fine preface by Professor Bezançon In the first chapter there is a good discussion of the contagiousness of tuberculosis and methods of preventing its spread Attention is called to the fact that in 1938 there were 870 dispensaries and 180 public or private sanatoriums, with 28,000 beds and 7,000 beds in hospitals for patients with pulmonary tuberculosis, together with 11,000 beds in public or private sanatoriums for patients with extrapulmonary tuberculosis In France the mortality from tuberculosis in 1934 was 131 per hundred thousand, while in the United States it was 57 per hundred thousand The author discusses the attempts France is making to control tuberculosis He believes the high mortality is largely due to lack of information of the public concerning this disease and recommends a larger and more intensive educational program In chapter 2 there is a thorough discussion of the prevention of tuberculosis among infants, and a number of cases are cited to prove his points The Grancher method of placing infants and children of tuberculous parents in homes free from tuberculosis is emphasized Chapter 3 is devoted to primary tuberculous infection both in children and in adults Here the author calls attention to the problem of tuberculosis among students of nursing and medicine Chapter 4 is devoted to a discussion of the prevention of tuberculosis in students The remainder of the book contains much information on the treatment and rehabilitation of tuberculous patients Throughout the pages of this book there are statistical data and numerous valuable facts It is a modern presentation The author is an internationally known worker in the field of tuberculosis His work has always been of a high quality, therefore this book can be recommended as an authoritative work

*Fractures of the Jaws* By Robert H Ivy MD DDS FACS Professor of Maxillofacial Surgery School of Medicine and Graduate School of Medicine and of Clinical Maxillofacial Surgery School of Dentistry University of Pennsylvania and Lawrence Curtis AB MD DDS Assistant Professor of Maxillofacial Surgery Graduate School of Medicine and School of Dentistry University of Pennsylvania Second edition Cloth Price \$4.50 Pp 192 with 199 illustrations Philadelphia Lea & Febiger 1938

The second edition of the textbook published in 1931 has required little change in the light of the authors' experience in the interim Twelve pages have been added together with alterations and additions to illustrations The chapter contributed by Leroy M Ennis, DDS, dealing with roentgenographic technic has been carefully revised The final chapter, on dietary management in fractures of the jaws, by Clyde W Scogn, DDS, remains essentially unaltered The material is logically organized A brief summary of clinically significant anatomic features is followed by a short general discussion of etiology, types, signs and symptoms of fractures The greater incidence of fractures of the mandible warrants the more extended space devoted to the lower jaw Statistics with respect to cause and location of fractures are based on a rather limited

number of cases It is interesting to note the increase from 8 to 25 per cent of fractures due to automobile accidents While dental splints are discussed, the exacting and time consuming technic is considered to be unnecessary in the treatment of most fractures Wiring of teeth in the same jaw or segments of both jaws with 24 gage brass wire utilizing the islet method or variation of it is advocated for common practice The use of one half round arch wire combined with the ligature procedure is highly recommended The use of orthodontic bands for attachment of arch wire segments to the teeth is considered of greater efficiency but with less favor because of the more specialized technic demanded The more recent American expositions of this method of fracture management are not included in the text or bibliography A very compact and useful summary of methods of fixation of fractures of the maxilla and mandible is furnished at the end of the respective chapters Management of more complicated fractures is concisely handled in a practical manner The plaster head cap with its adaptability of use is illustrated and the application of this device in retracting the angle of the mandible has clinical significance Similarly the use of the cannula for passing wires about mandibular fragments is deserving of careful attention for reference in the limited number of cases in which it is applicable The text is written in simple and direct style developed from a clinical point of view and should prove useful to dentists and surgeons who deal with this restricted field

## *Bureau of Legal Medicine and Legislation*

### MEDICOLEGAL ABSTRACTS

**Medical Practice Acts** Optometry as the Practice of Medicine—The plaintiff was licensed to practice medicine The board of registration in medicine revoked his license for "acting as principal or assistant in carrying on the practice of medicine with an unlicensed person" The trial court upheld the board and the plaintiff appealed to the Supreme Judicial Court of Massachusetts

The plaintiff and one Getter, a lay person, were associated in the optical business under the firm name of State Opticians and drew weekly equal amounts from the income of the business Advertising was in the firm name and glasses were furnished complete for a single price, there being no special charge for the examination The firm owned all optical instruments and equipment and paid all expenses All examinations were made by the plaintiff He used no drugs and performed no surgical operations but did only such acts as are included in the definition of optometry contained in the optometry practice act of Massachusetts

The single question before the court was whether the plaintiff was "carrying on the practice of medicine" within the meaning of the medical practice act When the legislature of Massachusetts first regulated the practice of optometry, it specifically defined that practice as "the employment of any method or means other than the use of drugs for the measurement of the powers of vision and the adaptation of lenses for the aid thereof" But this act, the court thought, was not an amendment of the law governing the practice of medicine, it set up an entirely new board for the examination and registration of applicants and regulated a field not regarded as already covered by statute Moreover, although the optometry practice act expressly exempted from its provisions physicians and surgeons "entitled to practice medicine in the commonwealth," it allowed them to be examined and registered as optometrists and it contained what to the court was this significant provision, "nor shall this act be construed to authorize any person to administer drugs in any form to practise or claim to practise medicine or surgery in any sense, or to use any title or appellation intended or calculated to indicate the practise of medicine or surgery" It was to the court difficult to believe that the legislature considered optometry, carefully defined in the optom-

etry practice act, as a part of the practice of medicine when in authorizing persons to practice optometry the legislature itself declared that it did not authorize them to practice medicine "in any sense." The exception of physicians from the operation of the act seemed to the court to have been due not to the belief that optometry as there defined was medicine but to the belief that there was no necessity for regulating qualified physicians who practiced in the field of optometry.

The court concluded therefore that the plaintiff, although a licensed physician, was not practicing medicine so far as his activities with the State Opticians were concerned. The decision of the board revoking the plaintiff's license was reversed—*Sachs v. Board of Registration in Medicine (Mass.)*, 15 N E (2d) 473.

## CENTRAL SOCIETY FOR CLINICAL RESEARCH

*Eleventh Annual Meeting Held in Chicago Nov 4 and 5 1938*

The President, Dr WILLIAM H BUNN, Youngstown, Ohio, in the Chair

(Continued from page 880)

### A Secretary Depressant in Human Gastric Juice

DRS ALEXANDER BRUNSCHWIG, JOHN VAN PROHASKA, T H CLARKE and ERNESTINE KANDLL, Chicago. In dogs with sub total gastric pouches and the nerves and vessels intact, intra venous injection of their own and other dogs' neutralized gastric juices produced no effect on the secretions of the pouch. The injection of gastric juices from nine of twelve patients with pernicious anemia produced periods of achlorhydria in the stimulation pouches. The juices from three of six patients with gastric cancer also produced periods of achlorhydria. Of a series of sixteen patients not having pernicious anemia or gastric cancer, three yielded juice which produced achlorhydria in the dogs. Boiling the "positive" gastric juices for ten minutes destroyed the secretory depressing factor.

### Effect of High Intracranial Venous Pressure on the Cerebral Circulation

DR EUGENE B FERRIS JR, Cincinnati. Five patients with obstruction of the superior vena cava and high venous pressure in the upper part of the body had no symptoms suggestive of cerebral anoxia or of high intracranial pressure, although in at least three the pressure of the cerebrospinal fluid was roughly the same as the venous pressure (from 22 to 50 cm of water). An estimate of the flow of cerebral blood in each of these patients was made by comparing the oxygen content of arterial blood with that obtained from the internal jugular vein. The arteriovenous oxygen differences did not vary appreciably from published normal values. The results indicate that venous hypertension does not diminish the flow of cerebral blood and does not of itself cause orthopnea. It is suggested that in the presence of high intracranial venous pressure the rigid covering of the craniovertebral cavity is the important factor in preventing sufficient venous distention and alteration in exchange of fluid between the blood and tissues of the brain to cause symptoms.

### DISCUSSION

DR JAMES A GREENE Iowa City. I think this work is important in the argument on the cause of cardiac dyspnea. Some of the members are familiar with the work of Dr Harrison, who performed experiments of obstructing the venous flow in the neck and did not produce dyspnea. He concluded from these experiments that increased venous pressure is not the cause of orthopnea. I think this study of Dr Ferris bears this out. It also shows that obstructing the venous flow from the brain does not interfere with cerebral circulation. If it does not interfere with cerebral circulation, one would not expect respiratory difficulty.

### Paroxysmal Auricular Tachycardia with Partial Auriculoventricular Block

DRS PAUL S BARKER, FRANK N WILSON and FRANKLIN D JOHNSTON, Ann Arbor, Mich, and SHELBY W WISHART, Evansville, Ind. Paroxysmal auricular tachycardia can usually be terminated by stimulation of the vagus or certain drugs. Rarely, instead of terminating the attack, stimulation of the vagus or administration of drugs will produce partial auriculoventricular block, slowing the ventricles while the auricular tachycardia persists. Six cases of this unusual manifestation have been studied electrocardiographically, some with precordial or esophageal leads. They are characterized clinically by unusually persistent tachycardia, high grade cardiac disability and the absence of the usual types of organic heart disease. Some patients responded well to digitalis or quinidin, while two died and came to autopsy.

### DISCUSSION

DR LOUIS N KATZ, Chicago. I should like to ask the authors whether they do not agree that the distinction between

auricular flutter and paroxysmal tachycardia in borderline cases is a matter of opinion and that in certain cases the distinction is arbitrary

DR FRANKLIN D JOHNSTON, Ann Arbor, Mich I agree with Dr Katz that in some cases the differentiation between auricular flutter and paroxysmal tachycardia is largely a matter of opinion The rate of auricular oscillation is probably the best guide available In flutter this rate is usually around 300 per minute, while in auricular paroxysmal tachycardia it is ordinarily between 150 and 200 per minute The form of the auricular waves is also helpful

#### Clinical Experience with Mercupurin in the Prevention of Acute Paroxysmal Dyspnea

DR EMMET FIELD HORINE, Louisville, Ky When paroxysmal dyspnea occurs with gross edema, there is no hesitancy on the part of most physicians in using mercurial diuretic preparations Cases of this type have not been included in this study Instead, thirty cases of distressing dyspnea but no manifest edema were selected Digitalization and thereafter administration of a maintenance dose of digitalis were inadequate in preventing recurrences of paroxysmal dyspnea A successful plan consisting of routine intravenous administration of mercupurin (mercurin with theophylline), in addition to diet and restriction of salt is described

#### DISCUSSION

DR WALTER W HAMBURGER, Chicago I should like to ask Dr Horine how he differentiates the results he obtained by mercupurin from those of salyrgan Mercupurin contains a purine derivative—theophylline—which salyrgan does not, and I feel that the theophylline radical rather than the mercurial portion of mercupurin gave these interesting results in paroxysmal dyspnea Both Drs Fred Smith and M H Nathanson obtained similar results with theophylline with ethylenediamine in paroxysmal dyspnea, and the effective agent in that preparation is this same theophylline which is contained in mercupurin

DR EMMET FIELD HORINE, Louisville, Ky In answer to the first question, concerning the difference between salyrgan and mercupurin, both are mercurial diuretic substances, though the latter contains, in addition, a small amount of theophylline I have used theophylline with ethylenediamine alone intravenously in an attempt to control paroxysmal dyspnea, but unsuccessfully That being true I am inclined to think it is the mercury radical and not the purine which accomplishes the results The reason I prefer mercupurin is that it is definitely less toxic, and further, I can repeatedly use the same vein without producing thrombosis I have not been able to do this with either salyrgan or merbaphen With reference to the question concerning loss of weight, the man whose chart was shown here was of large build and during the month under close observation lost over 30 pounds (13.6 Kg) There was undoubtedly considerable retention of fluid without manifest pitting edema of the extremities Apparently in certain persons paroxysmal dyspnea develops, as a result of retention of minimal amounts of edematous fluid—hence the successful results obtained through the use of mercupurin

#### Heart Failure in Subacute Bacterial Endocarditis

DRS WILLIAM C BUCHBINDER and OTTO SAPHIR, Chicago This study was undertaken to determine the frequency, intensity and chronicity of heart failure in subacute bacterial endocarditis Heart failure is frequently regarded as an important negative feature of the disease While we recognize sepsis, toxemia and progressive cachexia as the important clinical features, our observations clearly indicate that heart failure too is to be reckoned with A simple and serviceable explanation for the absence of signs of myocardial weakness is the often encountered general statement that the heart "somehow maintains its integrity in this disease Our observations, however, indicate that not only is heart failure evidenced clinically in a number of patients but morphologic changes in the cardiac muscle are encountered frequently if sought for In our material histologic studies show a high incidence of inflammatory and degenerative

changes in the cardiac muscle and particularly frequently small infarcts These are sufficient to explain the advent of heart failure

#### DISCUSSION

DR HAROLD FEIL, Cleveland Were there any abnormal electrocardiographic observations?

DR WILLIAM C BUCHBINDER, Chicago Most of our patients had electrocardiograms, but serial curves were secured in only a few instances These showed significant changes Rothschild, Sacks and Libman showed that patients with this disease had relatively few and insignificant changes in the electrocardiogram compared to those of patients with rheumatic carditis Serial curves were secured from the rheumatic group of patients, but the authors did not clearly indicate that they were obtained also from patients with subacute bacterial endocarditis From their conclusions, however, one must infer that they were Levy and Turner were careful to state that graphic records of the non-rheumatic group were taken at less frequent intervals They took records of 403 rheumatic patients and of twenty-three with subacute bacterial endocarditis With such a disproportionately large number of rheumatic patients, followed more systematically, a comparison of the two diseases in point of frequency of electrocardiographic alteration does not seem justifiable From the widespread changes occurring in the cardiac muscle as we found them, serial electrocardiographic curves would be expected to show significant alterations

#### Circulatory Disturbances Produced by Mediastinal Lesions

DR H CORWIN HINSHAW, Rochester, Minn A study has been made of the collateral circulation which develops as a result of compression of the great veins of the thorax Photography with infra-red rays has been used for studying and recording these phenomena Studies of venous pressure and of circulation time have also been carried out A wide variety of lesions may produce striking manifestations of circulatory disturbance Cases are illustrated in which such changes are associated with carcinoma of the bronchus, lymphoblastoma, intrathoracic goiter, mediastinal fibrosis, tuberculous lymphadenitis, metastasis from testicular carcinoma, rheumatic heart disease and chronic obstruction of obscure origin Both unilateral and bilateral obstruction are demonstrated

#### DISCUSSION

DR H CORWIN HINSHAW, Rochester, Minn In only one case at autopsy was the lesion definitely below the azygos vein It would appear logical from an anatomic standpoint that unless obstruction were above the level of the azygos vein the presence of collateral channels connecting with the internal mammary vein would be of no value

#### A Modification of the Grollman Method for Determining Cardiac Output

DR WRIGHT ADAMS and IRENE SANDIFORD, PH D, Chicago Grollman's method for determining cardiac output involves the collection of two samples of gas several seconds apart during deep rebreathing, from a lung bag system containing air and acetylene Lung bag equilibrium must be established before the first sample is taken and the second sample drawn before recirculation occurs The time of equilibrium and recirculation varies considerably, and there has been no good way of knowing how much a given determination was influenced by these factors By a technic which allows rapid frequent simultaneous sampling of alveolar gas and bag gas it is possible to obtain a figure for cardiac output with an individual evaluation of the errors in each case

#### DISCUSSION

DR LOUIS N KATZ, Chicago I should like to congratulate the authors on their ingenious modification of the Grollman technic I wonder whether Dr Adams has obtained any data with this method on patients with congestive heart failure and on patients with hyperthyroidism

DR FORD K HICK, Chicago I should like to ask whether this applies to pathologic cases

DR WRIGHT ADAMS, Chicago With regard to Dr Katz's question, we do not have enough observations to make a statement. In the application of the Grollman method to pathologic cases there have been several criticisms. Early recirculation and incomplete mixing are detected by this modification. We have had no experience with patients in heart failure but feel sure that this modification would offer no advantage in determining incomplete saturation of the blood with acetylene, owing to slow diffusion through edematous pulmonary tissue.

#### The Prognostic Significance of Hyperreactibility of the Blood Pressure in Normal Subjects

DR C A HINES JR, Rochester, Minn. A significant correlation was noted in many instances between the "ceiling" or maximum elevation of blood pressure with the cold pressor test and the first routine reading of blood pressure taken in the clinic. As records were available on a large group of patients who had returned to the clinic from ten to twenty years after their original reading of blood pressure I had an unusual opportunity to determine the significance of excessive reaction of the blood pressure to nervous stress in subjects with normal blood pressure. Data have been obtained from 1185 patients who returned to the clinic ten and twenty years after their first visit. Analysis of these data shows that the great majority (from 78 to 90 per cent) of the patients with an elevation of blood pressure on the original reading into the upper ranges of normal (140 to 150 systolic and 85 to 100 diastolic) had hypertension subsequently, whereas a small number (34 per cent) with an original reading within the lower range of normal (below 140 systolic and 85 diastolic) had hypertension subsequently. These observations are strong evidence that a hyperactive vascular system, as shown by excessive rises in blood pressure to stimulation, is the precursor of essential hypertension.

#### Do Eclampsia and Preeclampsia Cause Permanent Vascular and/or Renal Disease?

DRS WILLIAM J DIECKMANN and IRA BROWN, Chicago. Two or more pregnancies have been studied in 340 patients who have or have had toxemia of pregnancy. Analyses of blood and urine were also made. Our purpose was to determine whether eclampsia and preeclampsia caused permanent damage to the vascular-renal system or whether hypertension and/or albuminuria persisting after the puerperium might have been due to a preexistent or latent vascular-renal disease which was aggravated by the pregnancy. A number of patients with eclampsia and severe preeclampsia have been followed through subsequent normal pregnancies. Therefore it seems obvious that when permanent vascular-renal disease exists after these diseases it must have been produced by the pregnancy in a patient with a predisposition to hypertensive arterial disease. The classification of the so called toxemias of pregnancy into eclampsia, preeclampsia, essential hypertension, vascular-renal disease and acute or chronic glomerulonephritis is a satisfactory one.

#### DISCUSSION

DR LOUIS LEITER, Chicago. Those of the members who are confronted with the diagnostic problems connected with hypertension in pregnancy will realize that Drs Dieckmann and Brown have done good work in bringing these back into the realm of internal medicine. It is important to remember that chronic glomerular nephritis is as rare in the pregnant woman as in the nonpregnant woman. Chronic glomerular nephritis is rare, in contrast to essential hypertension. It is of great value to turn one's attention to the "hypertension of pregnancy" instead of the "nephritis of pregnancy." The authors have not gone into the question of the mechanism whereby pregnancy produces convulsive or nonconvulsive toxemia. I should like to hear their views on this point, particularly as to whether they think the disproportion of estrogenic and other hormones has anything to do with it. I should also like to ask whether there is any way of differentiating between women in whom eclampsia will and will not

develop in subsequent pregnancies. The question almost always comes up whether the patient should be allowed to go through another pregnancy, especially if the first or toxemic pregnancy does not result in a living child.

DR WILLIAM J DIECKMANN, Chicago. There are some changes in the estrogenic substances in toxemia of pregnancy, but we do not know whether they are the result or the cause of the toxemia. I believe the convulsions are caused by edema of the brain. The diagnosis of the type of toxemia is based on the history, time of onset in pregnancy, height of blood pressure response to medical treatment and course after delivery. The injection of 2 minims (0.12 cc) of solution of posterior pituitary causes an increase in the systolic blood pressure of more than 20 mm if the patient has preeclampsia. The "cold test" has little or no effect on a patient with this disease but produces an increase of 30 mm or more if the patient has essential hypertension or vascular-renal disease. Thus these two tests seem to be of diagnostic value.

#### Effect of Hypertonic Solutions on the Kidney

DRS HOWARD A LINDBERG, MAURICE H WALD and M HERBERT BARKER, Chicago. The possibility of inducing renal damage by the intravenous administration of hypertonic solutions, now popularly used in the therapy of many conditions, prompted this experimental study in dogs. Comparable doses to those administered clinically were given to the animals, and each experiment was controlled with a preliminary biopsy of the kidneys. Only one of these solutions caused anatomic changes. A single injection of the substance caused transitory renal damage, while repeated injections caused changes of a more enduring nature. The lack of associated urinary disorders or abnormalities of renal function to indicate this damage is discussed.

#### DISCUSSION

DR E P K FINGER, Rochester, Minn. I agree that too enthusiastic administration of hypertonic solution will cause damage to the kidney. However, I believe that if it is given judiciously in the lowest concentration great good can be done. I am in the habit of giving from 20 to 25 per cent and from 200 to 300 cc. I have observed cases in which the excretion of urea has been around 200 Gm a day and has come down without any hematuria or other ill effect. I am afraid there would be bad results from giving 1,000 cc of 50 per cent sucrose. Dextrose is secreted as sucrose, never in the concentrated form.

#### Urinary Specific Gravity

DR MAX MILLER, J W PRICE, PH D, and DR J M HAYMAN JR, Cleveland. Twenty-four hour specimens of urine from three patients with normal renal function on a constant diet and varying fluid intake were analyzed for total nitrogen, urea, ammonia, creatinine, organic acids and the inorganic constituents necessary for an acid base balance, and the effect of each of the constituents on the specific gravity of the urine was calculated. On a low protein (40 or 50 Gm) diet approximately 70 per cent of the observed specific gravity could be accounted for, while with higher protein (100 or 110 Gm) intake these constituents made up 85 per cent. Chloride had approximately the same effect (25 per cent) as sulfates and phosphates combined. Urea contributed more to the specific gravity on the high protein diet. Creatinine had only a negligible effect (from 1 to 2 per cent). The specific gravity unaccounted for was attributed to the organic acids and other organic compounds.

#### Pain, Location, Type and Reference in Primary and Secondary Peptic Ulcer

DR ANDREW B RIVERS, Rochester, Minn. Accuracy in diagnosis, always desirable, is particularly necessary when lesions involve the upper part of the gastrointestinal tract. A diagnosis of peptic ulcer is greatly facilitated if a careful study of pain, its location, type and reference is made. Much regarding the histologic condition of ulcer can be determined if a careful analysis of the location of pain, its type and the sec-

ondary areas of invasion are carefully noted. In the case of duodenal ulcer the pain is usually midepigastria; if the lesion is uncomplicated. In penetrating types of lesions there is usually a shift of pain to the right costal margin and frequently through to the back. In gastric ulcer the location of the pain is epigastric but there is a definite tendency toward a shift of this pain into the left costal margin and over the cardiac area. Occasionally high gastric ulcers have a shift of pain along the phrenic distribution into the neck. Gastrojejunal ulcers produce pain around the umbilical area, which in the case of perforation or deep penetration has a tendency to shift downward. The most likely location of recurring ulcers following surgical procedures is considered. The tendency toward recurrence after V-shaped resections of gastric ulcers, pyloroplasty and Billroth and Polya types of resection is considered, and the location of pain caused by such ulcers is discussed. I have slides indicating the various types of operations, with drawings of the most probable location of recurring ulcers as well as indications on these slides as to where the pain in such instances originates and into which secondary areas it shifts.

#### DISCUSSION

DR WALTER L PALMER, Chicago. May I ask Dr Rivers what his experience has been with regard to the significance of pain in the back? I think it is generally thought that pain in the back indicates perforation through to the pancreas. It seems to me that I have occasionally seen pain in the back when there has been no perforation. Does Dr Rivers feel that the severity of the pain is in direct proportion to or independent of the size of the lesion?

DR ANDREW B RIVERS, Rochester, Minn. If pain which has radiated from the epigastrium to secondary areas anteriorly also begins to be referred through to the back, this is usually indicative of a penetrating lesion. There are instances, however, of pain in the back in which the ulcer does not exhibit histologic evidence of penetration. The severity of the pain is not necessarily an indication of penetrating characteristics. Severe pain intractable to the usual methods of obtaining relief usually suggests invasion of the spinal sensory nervous system and hence assumes penetrative characteristics. However, pain relayed along the splanchnic nerves can be extremely severe.

#### Stabilization of the Diabetic Child

DRS R L JACKSON and J D BOYD, Iowa City. Data are presented to show that prolonged maintenance of aglycosuria is essential in estimating the insulin requirement of the diabetic child. By lengthening the period of observation under strict control, the final dosage level of insulin is materially reduced. Until stability has been established through such prolonged control, regulation is difficult and often ineffective in either the clinic or the home. Such an equilibrated patient serves as a suitable subject for the study of the effect of variations in therapeutic technique. In evaluation of various therapeutic regimens, conclusions often will be erroneous unless preliminary stabilization has been thorough.

#### DISCUSSION

DR SAMUEL SOSKIN, Chicago. The point which the authors make is important from an aspect which they have not stressed, that is, with reference to the experimental therapy of diabetes with substances other than insulin. I ran into the same problem six or seven years ago in adults, and the phenomenon is just as true for adults as for children. This phenomenon, I think, is responsible for many reports in the literature which purport to show that various drugs and the like are efficacious in cases of diabetes and on later study prove not to be so. Any one investigating the treatment of diabetes in adults or children should take note of this spontaneous improvement which invariably takes place in the hospital and should not ascribe the result to some unknown substance which is being tested. Obviously the time to test the unknown product is after the spontaneous improvement has ceased and the patient is stabilized.

DR ELMER L SEVRINGHAUS, Madison, Wis. I agree with the authors and with Dr Soskin that this is a general problem for all age groups. There are adults and children who show a

prolonged gain in tolerance during strict control. This cannot always be expected. Dr Wilder called my attention some ten years ago to the fact that frequently children who became diabetic actually showed an improvement like this, and then some time later, from six months to a year, showed a definite exacerbation of the diabetes without any obvious reason, such as infection or metabolic insult. I wonder whether the authors had opportunity to watch the children for long periods from six months to a year to see whether that happened in the hospital and to see what caused this loss of tolerance.

DR WALTER H NADLER, Chicago. Were these results obtained in any patients using the new insulin?

DR J W MOORE, Louisville, Ky. I should like to know what was done in the matter of diet.

DR RUSSELL M WILDER, Rochester, Minn. I want to congratulate the authors on the beautiful control of the glycemia of these diabetic children. If similar results are actually maintained in these patients after their return to their homes, the results are a challenge to the rest of the members to do better than we have. It will be extraordinarily difficult to persuade parents to leave their diabetic children in hospitals for periods as long as these, but if such great improvement in the stability of the sugar content of the blood can be obtained regularly, it should be insisted on. However, the authors ought to inform us about the duration of the diabetes in the cases they reported, because if they were dealing with early diabetes I should expect corresponding improvement of tolerance even with much less rigid management.

DR R L JACKSON, Iowa City. For the past twelve years, Dr Boyd has advocated the avoidance of glycosuria and the maintenance of normal values for blood sugar in diabetic children. The periods of hospitalization of these children were most frequently too short for the patients to have reached a relatively constant insulin requirement. Home management seldom led to improvement of the level of control at the time of discharge. Insulin shocks were frequent when the parents attempted to avoid glycosuria in these poorly equilibrated patients. Consequently a minority of our patients remained well controlled according to our standards. However, a few patients reached stability and remained stabilized for several years. When protamine zinc insulin entered the picture, we wished to compare its efficacy with that of regular insulin. Before making such comparisons we felt it necessary to attain maximum stability with regular insulin. It was found that several weeks of carefully supervised hospitalization was necessary for each subject to attain such a level of control. In each of the thirty-four patients who have been hospitalized in this manner we have observed the type of response described. In general, the longer the patients' glycosuria has been uncontrolled, the less the ultimate reduction of insulin dosage and the greater the difficulty in obtaining stability. In new patients the response is more prompt, and stabilization has been maintained under home management for many months. In no patients have exacerbations occurred without a demonstrable cause. We were unable to attain satisfactory stability when patients were given protamine zinc insulin before stabilization. However, once stability had been reached with regular insulin, we were able to maintain it on transfer to the protamine product if the total daily dosage had not exceeded 20 units and if the distribution of the diet had been changed. The status of the children under this regimen was less predictable than with regular insulin. Severe insulin shocks occurred occasionally, and in one instance such shock was fatal under home management. Using commercial supplies of zinc insulin crystals, we have found no appreciable prolongation of action over similar doses of regular insulin. By adequate diets we imply that the intake of protein, calories, vitamins and minerals has been prescribed with a view of meeting fully the patient's needs so far as modern nutritional knowledge directs. The child's height is used as a guide in determining his requirements. An immediate fatty acid dextrose ratio is employed, approximately 1 to 1½. The protein allowance provides a gram or more to the pound of theoretical body weight, as determined from the height.

## Current Medical Literature

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1928 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (\*) are abstracted below.

**Endocrine Manifestations in Juvenile Diabetes**—White presents data on 1,250 patients with juvenile diabetes (onset of the disease before the age of 15 years). In this group there were 177 patients who showed evidence of prolonged pituitary involvement. Of these 177 patients, 176 showed involvement related to the anterior lobe of the hypophysis (nine with signs of hyperactivity and 168 with signs of hypo activity). Among these patients were ninety-four dwarfs, twenty-two with Frohlich's syndrome and fifty-one with signs of infantilism. Only one patient had signs and symptoms related to the posterior lobe of the hypophysis. None of the 1,250 patients showed signs of deficiency of the thyroid gland, three had signs of hyperthyroidism, one had possible adrenal disturbance and twenty-eight had lesions related to the gonads. All presumably showed hypofunction of the pancreas, but two presented signs of hyperinsulinism in addition. Sixty-five had disturbances of the liver which may or may not have been of endocrine origin. In conclusion, the author states that the juvenile patient shows evidence of a disturbed hormone balance. There is striking evidence of hyperactivity of the pituitary body in the prediabetic stage, followed by diminution of activity which in its most extreme form occurs in the diabetic dwarf.

**Blood Carotene in Man**—Curtis and Kline studied the effect in man of various amounts of ingested liquid petrolatum on the absorption of carotene from the gastrointestinal tract, as measured by determinations of blood carotene. It was observed that liquid petrolatum given in amounts of 20 cc three times daily or twice daily before meals, or mixed with carotene dissolved in cottonseed oil prevents complete absorption of carotene from the ingested material. In this respect these experiments compare with those of Dutcher and his colleagues, of Mitchell and of Jackson. The rise of blood carotene is much more rapid when carotene is fed dissolved in vegetable oil than when a diet containing large amounts of carotene is given. The fall in blood carotene is much more rapid when it is mixed with liquid petrolatum than when liquid petrolatum and high carotene foods

are given. The mixture of the carotene in oil with liquid petrolatum must then be responsible for this change. The authors believe that their experiments confirm Jackson's conclusion that a greater depletion of carotene occurs when carotene foods and liquid petrolatum are mixed than when they are fed separately. When the total amount of liquid petrolatum is decreased from 60 cc daily to 40 cc daily but the oil is still given in 20 cc doses before the morning and the night meal, the diversion of carotene seems to be as pronounced as when 20 cc is given three times daily. When a total of 30 cc of liquid petrolatum is given to a patient on an apparently "empty" stomach, there seems to be little if any effect on the absorption of carotene from the gastrointestinal tract, as measured by the blood carotene. Little if any effect on the blood carotene is demonstrated when the liquid petrolatum is given in a single dose of 30 cc at bedtime. The authors believe that if liquid petrolatum is administered at a time of the day when it may be mixed with food in the gastrointestinal tract it interferes with the absorption of carotene.

**Primary Carcinoma of the Lung**—Hochberg and Lederer observed a group of patients with a history of thoracic symptoms of less than one month's duration and a group of patients without thoracic symptoms for whom a final diagnosis of carcinoma of the lung was made. On the basis of these cases the earliest manifestations of the disease are emphasized. Between 1917 and 1936 inclusive there were admitted to the Jewish Hospital of Brooklyn 170 patients with carcinoma of the lung, forty-seven of whom were free from thoracic symptoms until about one month before admission and another thirteen gave no history referable to the thorax. It is this group of sixty patients which forms the basis of the authors' study. There is no doubt that a certain number of cases of carcinoma of the lung will continue to escape recognition until late in the course of the disease, not merely because patients delay medical attention and because the disease produces symptoms mimicking those of other diseases and therefore is not readily recognized but because the first symptoms to attract the patient's attention are due to metastatic deposits. In the present series of cases epigastric distress, nausea, vomiting, pruritus, dysuria and hemorrhoids were not infrequently encountered as the initial complaints. There are no signs or symptoms pathognomonic of early carcinoma of the lung. A change in the habit of coughing or in the character of the expectoration or paroxysmal dyspnea without apparent cause requires a careful examination of the thorax before carcinoma of the lung is ruled out. The accessory means of diagnosis of early carcinoma of the bronchus, in the order of facility and diagnostic importance, are bronchoscopic examination and biopsy of tissue removed bronchoscopically, study of the pleural effusion, puncture of the lung exploratory thoracotomy and biopsy of an accessible metastatic nodule.

**Epinephrine in Oil**—Keeney and his co-workers prepared epinephrine in oil by suspending powdered epinephrine in peanut oil. It is so prepared that 1 cc of oil contains 2 mg of epinephrine. This preparation is absorbed slowly. Ten patients with chronic asthma who had been taking frequent daily injections or inhalations of epinephrine hydrochloride received relief from asthmatic symptoms for from eight to sixteen hours with from 0.65 to 2 cc doses of epinephrine in oil. One patient received no prolonged effect from adequate doses. Eleven patients were treated during one or more acute paroxysms of asthma. Each received from 0.5 to 1.5 cc of epinephrine in oil and remained free from asthma for from nine to sixteen hours, but more generally for twelve hours. For one patient with urticaria and another with serum sickness, epinephrine in oil provided relief from symptoms for twelve hours. The hyperglycemic response to epinephrine in oil was maintained in five cases for at least eight or nine hours, while the response to epinephrine hydrochloride, though more marked, was usually over in three hours. The cardiovascular response to epinephrine in oil in three cases was maintained for eight or nine hours, while with epinephrine hydrochloride it is generally over in from forty-five to ninety minutes. The single injection of epinephrine in oil is preferably made subcutaneously. Consecutive subcutaneous injections are irritating in some cases, but numerous intramuscular injections can usually be made without discomfort.

**Effect of Dinitrophenol on Cardiac Output**—Under careful supervision, Stewart and his associates gave 2 4 dinitrophenol to two obese patients and studied its effect on their circulatory system. The administration of dinitrophenol (varying from 150 to 275 mg daily) in the first case raised a normal basal metabolic rate to +36 per cent and resulted in a slight increase in cardiac output, a greater increase in arteriovenous oxygen difference and essentially no change in the velocity of blood flow. There was no change in the size of the heart, venous pressure and vital capacity. Both systolic and diastolic blood pressures were slightly lowered. In the second case dinitrophenol (from 50 to 300 mg daily) resulted in an increase in oxygen consumption so that the basal metabolic rate rose from 0 and —3 to +22 per cent. The cardiac output and the arteriovenous oxygen difference were increased. The circulation time was decreased. There was no significant change in the size of the heart, venous pressure and vital capacity. The blood pressure was slightly elevated.

**Acute Phlegmonous Gastritis**—Lyall prefers the term acute cellulitis of the stomach to phlegmonous gastritis. He reports seven cases which show that the condition is not always fatal. Recovery occurred in two of his cases and in one reported by Marshall (1935). Such healing may play a part in the etiology of gastric cirrhosis. In the author's two cases the disorder was associated with gastric ulcer. He imagines that a slight degree of this cellulitis is not uncommon in association with peptic ulcer, especially one which has been showing recent acute activity and has perforated. The friability of the gastric wall around certain perforations, making the insertion of the "purse-string" suture difficult, is probably due to spread of infection for some distance round the ulcer. The danger of performing a partial gastrectomy in such cases and thus cutting across infected tissue is obvious. The closure of the perforation by a plug of omentum, as in one of his cases, appears to be the safer procedure. Certain possibilities in the etiology of the condition discussed by the author are infection through a break in the gastric mucosa, poisons and hematogenic infection.

- Primary Mortality of Infants Relations to Weight of Fetus and Etiology H Bjerre—p 438

**Intravenous Antispasmodic in Cervical Spasm of Child-birth**—Fournier describes several cases of breech presentation in which a spasmodic contraction of the cervix incarcerated the after-coming fetal head and in which the spasm did not yield until after the fetus was asphyxiated. These cases raised the problem as to how to overcome this cervical spasm within a relatively short time so as to safeguard the life of the infant without increasing the maternal risks. The author shows that the different therapeutic methods which have been recommended for this purpose, such as chloroform anesthesia, anterior or posterior incision of the cervix or the use of the forceps, are either ineffective or involve dangers for the mother. In order to save the mother, the infant is frequently sacrificed in these cases. It was decided to try antispasmodic medication under these conditions. Since it is essential to exert the antispasmodic action quickly, it is necessary to administer the antispasmodic in comparatively large doses and by way of the blood stream. The author cites some of the cases in which he administered 1 cc of an antispasmodic preparation by intravenous injection and in which it was found that from thirty to sixty seconds later the after-coming head could be extracted and the infant could be revived. This method of antispasmodic medication, which was introduced by Schuckele and his students, proved successful without provoking material lesions and without losing a single child. The author says that in six cases he injected the antispasmodic during general anesthesia and in one case in the absence of anesthesia. In one instance the injection was repeated after an interval of ten minutes.

## Prensa Medica Argentina, Buenos Aires

26 81 134 (Jan 11) 1939 Partial Index

- Supernumerary Kidney Case T E Grimaldi—p 81
- Value and Interpretation of Frey's Hysterotonography T A Uranga Imaz—p 96
- \*Hydramnios in the Clinic R Dubrovsky and N O di Fonzo—p 102

**Hydramnios**—Dubrovsky and di Fonzo observed hydramnios in 20 pregnant women out of a group of 38,500 who were cared for at the maternity hospital of Buenos Aires from 1928 to 1936. The condition was of slow evolution in 162 cases and acute or subacute in forty-seven. There was syphilis in thirty-nine cases, twin pregnancy in twenty-two, hydriops in thirty-two, renal toxicosis in ten, heart disease in eight and diabetes in six. Eighty-eight women were normal except for the presence of hydramnios. There was practically the same proportion of chronic hydramnios in primiparas and multiparas (eighty and eighty-two cases respectively). In the majority of cases the clinical and serologic examinations for syphilis gave negative results. In the group of pregnant women with hydramnios of slow evolution, two women were discharged during pregnancy. There were thirteen twin pregnancies, twenty-five women had premature deliveries and 124 carried pregnancy to or near full term. In the group of acute and subacute hydramnios there were eight twin pregnancies. Twenty-six pregnancies were carried to or near full term. In the whole group of 207 cases there were abnormal presentations in thirty-five, disturbances of the dynamics of the uterus in eighty, proclitonia of either the umbilical cord or an arm in five cases, atony for delivery of the afterbirth in twenty-six cases. The mortality was fifty-one fetuses. In fourteen cases there was anencephalus or hydrocephalus. According to the author a careful clinical examination is indicated in the presence of hydramnios for the diagnosis of either twin pregnancy or fetal malformations. If the clinical examination fails an x-ray examination is indicated. The treatment of hydramnios consists in hygiene, a proper diet and rest for the patient. Antisyphilitic treatment has to be resorted to

only after proper indications, as syphilis is a causal factor in only a small proportion of cases. Puncture of the uterus for elimination of hydramnios improves the condition of the mother. However, generally it is followed by spontaneous abortion. The administration of mercurial diuretics is of value in many cases. The administration of intravenous injections of solution of posterior pituitary is of value in the presence of inertia, except when there are contraindications.

- Use of Nitrogenic Components of Blood in Diagnosis of Urologic Diseases L Sas—p 317
- Pathogenesis of Acute Thrombopenic Purpura A Vogl—p 325

**Anacidity of Diabetic Patients**—Fenz points out that the relations between the gastric secretion and the diabetic disturbance in the metabolism have been repeatedly investigated in recent years and it was found that, whereas hypoglycemia is usually accompanied by an increase in the hydrochloric acid content, hyperglycemia is accompanied by a decrease. In view of the great significance of the diabetic inhibition of acidity and of its relation to insulinization, the author studied the gastric secretion of 116 unselected cases of diabetes mellitus with the aid of the caffeine test breakfast. He detected anacidity in sixty-five (56.3 per cent), hypo-acidity in twenty (17.2 per cent) and normal acidity or hyperacidity in the others. That insulinization cannot be the cause of the frequent anacidity was proved by the fact that anacidity was more frequent in untreated diabetic patients than in those who had received insulin, even quite new cases often showed complete anacidity. When insulin was administered during the caffeine test breakfast, the acidity curve increased in patients with normal acidity and hypo acidity, especially when a hypoglycemic shock resulted. Diabetic patients who readily respond to insulin are more often subject to anacidity than are those who are resistant to insulin, but the latter show hyperacidity more often than do those who are sensitive to insulin. The severity of the diabetes does not determine the appearance of a diabetic anacidity. It was found that forty-four of the 116 patients had the typical diabetic diarrheas. The fact that 70.5 per cent of those with diarrheas had anacidity and that among those with severe diarrheas the percentage of anacidity reached 78 seems to indicate that the diabetic diarrheas can be regarded and should be treated as gastrogenic diarrheas. Discussing the causes of diabetic anacidity, the author suggests that deviations in the relationship between insulin and counterregulation, to the disadvantage of insulin, probably play a part. It has been suggested by Falta that in those who are resistant to insulin the diabetic disturbance in the metabolism is not so much the result of an insulin deficiency as of an excessive counterregulation. Thus it is understandable that the hypo acidity, which apparently is due chiefly to an insulin deficiency, is less noticeable in these resistant cases than in the diabetic patients who are sensitive to insulin.

- Difficulties in Blood Group Determination A Pondman—p 6111

**Prevention of Abortion**—Looijen says that practical observation proves that abortions take place chiefly during the so called menstrual weeks, that is, at the times when menstruation would otherwise have occurred. This seems to indicate that even during pregnancy the female organism is under the influence of the cyclic changes. He cites several cases in which threatened abortion was averted by rest in bed and by the administration of progesterone. In some of the women the difficulties recurred for several months at the time when otherwise menstruation would have taken place. Whenever this was the case, the injections of progesterone were repeated. Abortion was thus prevented and the pregnancy could be brought to term.

## TREATMENT OF PNEUMOCOCCIC PNEUMONIA WITH SULFANILAMIDE

ALVIN E PRICE M D  
AND  
GORDON B MYERS, M D  
DETROIT

Sulfanilamide has proved bacteriostatic against types I, II, III and XIV pneumococci in vitro and in laboratory animals, according to various authors.<sup>1</sup> While the drug probably has been used widely for human pneumococcal pneumonia, the reports to date are meager. Heintzelman, Hadley and Mellon<sup>2</sup> used it in nine cases of type III pneumonia and obtained seven recoveries, whereas among ten controls there were only two recoveries. Millett<sup>3</sup> reported one case of type III pneumonia in which a crisis occurred after the use of sulfanilamide. Louis<sup>4</sup> added six cases of pneumococcal pneumonia in which recovery occurred with sulfanilamide therapy.

The following report is based on 115 patients treated with sulfanilamide, compared with forty patients receiving serum and ninety-four controls receiving identical symptomatic and supportive measures but no specific therapy. While this series is too small to be statistically significant, it is reported in the hope that an evaluation of the drug in the treatment of pneumonia may eventually be made by combining it with cases studied elsewhere.

### METHOD OF STUDY

**Diagnosis**—The diagnosis was confirmed by roentgenogram in every case. The admission sputum was typed directly by the Neufeld method, and the results

This study was aided in part by a grant from the Commonwealth Fund From the Medical Department of the City of Detroit Receiving Hospital and Wayne University College of Medicine

were checked either by mouse inoculation or by the direct typing of a second specimen. Typing was repeated in the event of an extension. Blood for culture was taken on admission and cultures were repeated daily if positive. Hemoglobin estimations, white cell counts and differential counts were made daily during sulfanilamide therapy and at frequent intervals for the controls. Red cell counts were made twice weekly. Serum agglutinins were determined during convalescence.

**Selection of Cases**—All patients over 12 years of age with pneumonia due to a single type of pneumococcus who were admitted between Oct 1, 1937, and July 1, 1938, and remained in the hospital at least twenty-four hours were included in this study. Children under 12 were excluded because childhood and adult pneumonias are not strictly comparable. Patients who were moribund on admission and died within twenty-four hours were excluded because it was felt that they did not provide a fair trial of any form of therapy. Eight such patients were treated with sulfanilamide, three with serum and eight as controls. Two other patients treated as controls for three and six days respectively, with sulfanilamide therapy started within eight hours of death, were excluded from the tabulations.

Alternate patients with types I, II and VII pneumonia were treated with sulfanilamide and Felton serum, a few being reserved as controls. With types V and VIII pneumonia, serum was available for only a portion of the patients alternated with those receiving sulfanilamide. With the remaining types, patients receiving sulfanilamide were alternated with controls, who received similar symptomatic and supportive treatment. If for any reason the type could not be determined promptly, the patient was classed tentatively among those having nonpneumococcal pneumonia, who likewise were treated alternately with sulfanilamide. For several of these patients the type of invading pneumococcus was subsequently determined, thus causing discrepancies in the total number of patients treated by the two methods.

**Dosage of Sulfanilamide**—The oral route was used as a routine, subcutaneous injections being substituted with those too ill to take or retain the drug by mouth. An initial massive dose of 15 grains (1 Gm) to 20 pounds (9 Kg) of body weight was given to all patients, those over 160 pounds (73 Kg) receiving the maximum dose of 120 grains (8 Gm). A similar total (15 grains to 20 pounds) was administered during the next twenty-four hours, divided into six equal doses, the first given four hours after the initial massive dose and the remainder at intervals of four hours around the clock. An equal amount of sodium bicarbonate accompanied each dose of sulfanilamide. The blood sulfanilamide

level was determined within the first twenty-four hours and daily thereafter. An attempt was made to keep the blood concentration between 7 and 15 mg per hundred cubic centimeters but preferably above 10 mg. As long as it was within this range, 15 grains to 20 pounds divided into six equal doses was given during each subsequent twenty-four hour period. If the blood level did

changes in the blood picture, treatment with sulfanilamide was discontinued and transfusions were given.

*Treatment of Patients Receiving Serum and of Controls*—This treatment was similar to that described by one of us (A. E. P.) in a previous communication, except that serum was given in larger doses at intervals of two hours. The average total dose for type I pneu-

not reach 7 mg per hundred cubic centimeters, either the subcutaneous route was substituted or a larger dose was given by mouth. In most instances administration of the drug was discontinued after the temperature had been normal for twenty-four hours. If blood levels were maintained between 7 and 15 mg per hundred cubic centimeters for five days without definite clinical response the case was classed as a therapeutic failure and the drug therapy was stopped. At the advent of serious toxic manifestations, particularly jaundice and

pneumonia was 210,000 units, for type II, 255,000, for type V, 124,000, for type VII, 175,000, and for type VIII, 110,000 units.

## SUMMARY OF CASES

*Race, Sex and Age*—Most of the significant data for the sulfanilamide, serum and control groups have been summarized in table 1. The racial distribution was as follows: sulfanilamide group, white 63.5 per cent and Negro 36.5 per cent; serum group, white 72.5

per cent and Negro 27.5 per cent, controls, white 67 per cent and Negro 33 per cent. The proportion of males in the sulfanilamide group was 80.9 per cent, in the serum-treated group 82.5 per cent and in the controls 77.7 per cent. The age distribution was not as even as desirable, the average for the sulfanilamide group being 38.7 years as compared with 39.9 years for the serum-treated patients and 45.6 years for the controls.

**Associated Diseases**—A history of daily consumption of alcohol was obtained from 30.4 per cent of the patients treated with sulfanilamide, from 22.5 per cent of those treated with serum and from 23.4 per cent of the controls. The Kahn reaction of the blood was positive for 23.5 per cent, 10 per cent and 14.9 per cent respectively. In the sulfanilamide group there was one patient with recent coronary thrombosis and four patients with congestive heart failure. The failure was secondary to hypertension in one, coronary sclerosis in two and syphilitic heart disease in one. There were four additional patients with definite clinical evidence of heart disease which remained compensated throughout their hospital stay. One of the patients treated with serum had failure of the right ventricle secondary to rheumatic mitral stenosis, another had well compensated mitral stenosis. Among the controls there were four patients with congestive heart failure secondary to hypertension and four others with com-

**Duration and Extent of Pneumonia**—The average duration of the pneumonia before treatment was ninety-two hours in the sulfanilamide group, 59.1 hours for the serum-treated patients and 71.7 hours for the controls. The average number of lobes consolidated, as determined from the admission roentgenogram, was

1.53 in the sulfanilamide group, 1.16 in the serum group and 1.51 in the controls. The incidence of bacteremia was 19.1 per cent in the sulfanilamide group, 30 per cent for those treated with serum and 14.7 per cent for the controls. The admission leukocyte count was below 7,000 for four patients of the sulfanilamide group, for three serum-treated patients and for nine controls, and between 7,000 and 10,000 for twelve, four and eighteen patients, respectively.

## RESULTS

**Effect of Sulfanilamide on Temperature**—In table 2 the patients treated with sulfanilamide have been classed according to the number of hours elapsing between the commencement of the drug therapy and defervescence. The temperature fell to normal within twenty-four hours of the onset of sulfanilamide therapy in twenty-six cases (22.6 per cent), within forty-eight hours in fifty-one cases (44.3 per cent) and within 120 hours in eighty-five cases (73.9 per cent). On the other hand, the temperature reached normal within forty-eight

pensated hypertensive or arteriosclerotic heart disease. Two controls and two of the patients treated with sulfanilamide had chronic asthmatic bronchitis. One of the patients treated with sulfanilamide had a compound fracture complicated by osteomyelitis, which was an important contributory factor toward his death. One of those in the control group had a carcinoma of the colon. The remainder had no associated diseases which were likely to affect the prognosis.

hours in only 16 per cent of the control cases. The effect of sulfanilamide on temperature was most striking when administration was started within thirty-six hours of the onset of the pneumonia. In fifteen of twenty-five such cases, the entire duration of the pneumonia, from onset to defervescence, was less than seventy-two hours. An example of an abortive crisis following sulfanilamide therapy is given in chart 1 and table 3 (case 1).

Twelve patients who did not show a temperature response within 120 hours but subsequently recovered from the pneumonia were classed as sulfanilamide failures. An example is given in chart 2 and table 4 (case 2). In this case, the blood culture became negative and a pseudocrisis occurred within twenty-four hours of the commencement of sulfanilamide therapy. In spite of adequate blood levels, the fever returned and the pneumonic process extended. The patient finally recovered, long after administration of the drug had been discontinued. Of the eighteen patients who died, two had had a pseudocrisis, whereas the other sixteen showed no definite temperature response.

three of fifteen controls (20 per cent) and for seven of twelve patients (58.3 per cent) treated with serum. For those responding to sulfanilamide the blood culture usually became negative within twenty-four hours of the onset of therapy. The results were particularly good with type XIV, all four patients recovering. One of the most dramatic results is illustrated in chart 3 and table 6 (case 3). The patient was admitted on the seventh day of illness and was given no specific therapy during the first five days in the hospital. He showed roentgenographic evidence of an extension on the tenth day and positive blood cultures on the seventh, ninth, tenth and eleventh days. He was given a massive dose of sulfanilamide on the twelfth day and eight hours later had a crisis, eventually making a complete recovery. In chart 4 and table 7 (case 4) the course of type II pneumonia and bacteremia in a chronic alcoholic addict is illustrated. Sulfanilamide was started on the second day of illness. The blood culture was negative the following day and the temperature was normal from the fourth day. In chart 5 and table 8 (case 5) the course

In table 2 an attempt was made to correlate the temperature effect with the blood sulfanilamide level at the time of defervescence. No significant difference was noted between the group with blood sulfanilamide concentrations over 10 mg per hundred cubic centimeters and the group with levels between 7 and 9.9 mg. When no therapeutic response occurred at low levels, larger doses were purposely given. One patient was observed who showed no improvement during three days when the blood level fluctuated between 4 and 7 mg per hundred cubic centimeters but had a fairly prompt crisis after it rose to 10 mg. There were no definite examples of therapeutic failures at blood levels of from 7 to 9.9 mg per hundred cubic centimeters followed by responses at higher levels. However, a much larger series will be needed to determine the optimal blood sulfanilamide concentration.

The effect of sulfanilamide on the pulse rate roughly paralleled that on the temperature. In some patients there was an associated symptomatic improvement but in many this was masked by the lassitude produced by the drug.

**Effect of Sulfanilamide on Bacteremia**—The results in the cases of pneumococcic pneumonia complicated by bacteremia are given in table 5. For twenty-one of the patients treated with sulfanilamide the blood culture was positive on admission, and for seventeen (81 per cent) it became negative during treatment. On the other hand, the blood culture became negative for only

of type V pneumonia and bacteremia treated with sulfanilamide is illustrated. The blood was sterilized promptly and the temperature fell by lysis.

Five patients whose blood cultures became negative with treatment subsequently died. Three of these were in the sulfanilamide group, one in the serum group and one among the controls. In one of those whose blood culture became negative with sulfanilamide therapy, hemolytic anemia subsequently developed, making it necessary to discontinue use of the drug. Ten days later the blood culture again showed the same organism and pneumococcic meningitis developed. At autopsy, it was seen that the pneumonia had completely resolved.

**Effect of Sulfanilamide on the Consolidation**—Daily physical examinations were made to detect extensions and complications of the pneumonic process. The physical appearances were checked as often as necessary by x-ray examination. X-ray evidence of extension during sulfanilamide therapy was obtained in twelve cases (10.4 per cent), during serum therapy in six cases (15 per cent) and in eight control cases (8 per cent). Nine of the twelve patients in whom extensions developed during sulfanilamide therapy eventually recovered. The patients were also followed to determine the completeness of resolution. The consolidation cleared up in all but one of the patients classed as recovered. This patient still had evidence of unresolved pneumonia five months after sulfanilamide therapy had been discontinued. The effect of sulfanil

amide on the sputum will be reported by Dr. Arthur W. Frisch in a separate communication.

**Effect of Sulfanilamide on Complications**—The incidence of empyema was 17 per cent in the sulfanilamide group, 10 per cent for the serum-treated patients and

21 per cent for the controls. More frequent than empyema were small pleural effusions, which did not become purulent and eventually disappeared without surgical intervention. The incidence of these in the three groups was 4.3 per cent, 7.5 per cent and 5.3 per cent respectively. None of the patients in this series had lung abscess or pericarditis.

**Effect of Sulfanilamide on Mortality**—The mortality rate for the 115 patients treated with sulfanilamide was 15.7 per cent and for the ninety-four controls was 30.8 per cent. The death rate in fifty-seven cases of types I, II, V, VII and VIII pneumonia treated with sulfanilamide was 10.5 per cent, whereas it was 27.5 per cent in forty cases of the same types treated with serum. While these figures are favorable to sulfanilamide, they are inconclusive because of the small number of cases, unevenly balanced as to type as well as to the following factors. The age distribution favored sulfanilamide. Likewise, the proportion of patients with leukopenia was lower in the sulfanilamide group. These factors were partly balanced by the longer average duration before treatment and the higher incidence of alcoholism, particularly delirium tremens, in the sulfanilamide group. The average extent of the consolidation was nearly equal in the sulfanilamide and control groups

and considerably less in the serum group. The incidence of bacteremia was highest in the serum group and lowest in the controls.

The mortality for pneumonia complicated by bacteremia is given in table 5. The mortality rate was 33 1/3 per cent for the patients treated with sulfanilamide, 50 per cent for those treated with serum and 86.6 per cent for the controls.

The results with type II pneumonia were particularly encouraging. Among eighteen patients treated with sulfanilamide there were 16.6 per cent of deaths, as compared with a mortality of 42.9 per cent for fourteen patients treated with serum. The results with the other types are given in table 1 and will not be discussed further because of the small number of cases of each type.

#### TOXIC MANIFESTATIONS

**Cyanosis**—This developed in practically every patient treated with sulfanilamide. There was no apparent correlation between the depth of the cyanosis and the outcome in the case. Many patients with deep cyanosis made satisfactory recoveries. It has been shown that sulfanilamide cyanosis is usually due to blood pigmen-

Vomiting and diarrhea were rare. Jaundice was present in the six patients in whom hemolytic anemia developed. In one other (chart 2 and table 4) toxic hepatitis developed. Since there was a coincidental extension of the pneumonia, the hepatitis may have been due to the pneumococcal infection.

*Cerebral Manifestations*—Lassitude, headache and drowsiness were common toxic manifestations. Delirium developed in fourteen patients treated with sulfanilamide. With nine of these a history of chronic alcoholism was elicited and the clinical picture was typical of delirium tremens. With the other five it could not be definitely determined whether sulfanilamide or the pneumonia itself was responsible for the delirium.

*Fever and Rash*—While it was frequently difficult to distinguish between fever due to sulfanilamide and that due to the disease itself, there were seven instances in which the fever continued in spite of apparent clinical improvement. In these cases the temperature tended to reach a peak in the early morning and fell in the afternoon. The fever subsided in all seven cases soon after administration of the drug was stopped. In two of the cases a morbilliform rash accompanied the fever.

*Anemia*—In six of the patients treated with sulfanilamide acute hemolytic anemia developed, an incidence of 52 per cent. The total fall in hemoglobin content exceeded 4 Gm per hundred cubic centimeters and the total fall in red cells was in excess of 1,500,000 per cubic millimeter in each case. The anemia developed abruptly in every case, appearing on the second day of

sulfanilamide therapy in one case, on the third day in four and on the fifth day in one. In every case the hemoglobin content and red cell count continued to fall for two to three days after the drug therapy was discontinued. One patient had pneumococcal meningitis ten days after the onset of the anemia and died. The other five patients made a complete recovery with the aid of blood transfusions. Four returned for check counts some time after discharge. In one there was no appreciable change in the blood picture two months afterward. In the other three the check blood count was normal.

An example of acute hemolytic anemia developing after 170 grains (11 Gm) of sulfanilamide is given in chart 6 and table 9 (case 6). The patient had type XIV pneumonia with bacteremia and leukopenia and was considered moribund at the time use of the drug was started. Within two days marked leukocytosis developed and the blood culture became sterile. A complete recovery eventually occurred. A similar abrupt neutrophilic leukocytosis accompanied the hemolytic anemia in four of the five remaining cases. This may prove a valuable warning sign.

In twenty-one additional cases (182 per cent) a more gradual and moderate fall in the hemoglobin con-

tent (between 2 and 4 Gm per hundred cubic centimeters), with a comparable fall in the number of red cells (between 500,000 and 1,500,000 per cubic millimeter) occurred. In twelve of these the anemia appeared during the administration of sulfanilamide, and in the other nine it developed after the drug therapy was discontinued. Nine of the twenty-one patients had check blood

counts some time after discharge. One, who returned in two weeks, showed no change whereas the other eight, who returned after longer intervals, showed a satisfactory response. Thirty of the sulfanilamide group in whom anemia did not develop while they were in the hospital also returned for check blood counts after discharge. In every instance the blood count was as high as or higher than at discharge.

Acute hemolytic anemia was not observed among the control patients or serum-treated patients. Moderate secondary anemia developed in 11.6 per cent of such patients for whom adequate hematologic records were kept.

**Leukocytosis**—In none of the patients treated with sulfanilamide did granulocytopenia develop. In all four of the patients with an initial white cell count below 7,000 leukocytosis developed during sulfanilamide therapy, whereas six of the twelve whose initial count was between 7,000 and 10,000 showed a distinct rise after the drug therapy was started. The leukocytosis may have been due either to the infection or to liver extract, which was administered simultaneously to some of the patients, rather than to sulfanilamide. The abrupt leukocytosis which accompanied hemolytic anemia, however, was probably due to sulfanilamide.

#### COMMENT

While the results with sulfanilamide are encouraging, its place in the treatment of pneumonia has not been definitely determined. The future trend will probably be toward a combination of serotherapy and chemotherapy, particularly with types II and III. Osgood<sup>9</sup> found that a combination of sulfanilamide and serum was more effective against pneumococci in human bone marrow cultures than either preparation alone. We have used the two simultaneously in two cases of type I, in one case of type V and in two cases of type VII pneumonia without a fatality and in five cases of type II with one death.

Concerted efforts are being made to prepare derivatives that are more effective than sulfanilamide against the pneumococcus. Whitby<sup>10</sup> recently reported that sulfapyridine (2-[p-aminobenzene-sulfonamido] pyridine) will protect against minimum lethal doses of 10,000 pneumococci of types I, VII and VIII and against slightly smaller numbers of pneumococci of types II, III and V. Evans and Gaisford<sup>11</sup> reported a mortality rate of 8 per cent for 100 patients treated with this drug as compared with 27 per cent for 100 controls. Their results are unconvincing, however, since they are not analyzed from the standpoint of type, duration before treatment, extent of consolidation and incidence of bacteremia. Good results have been obtained in the laboratory with various sulfones.<sup>12</sup>

#### SUMMARY

This preliminary report is based on 115 cases of pneumococcic pneumonia treated with uniform doses of sulfanilamide and alternated with forty cases treated with Felton serum and ninety-four controls who

received no specific therapy. The results were analyzed from the standpoint of the type of pneumococcus, average age of the patients, duration of the pneumonia before treatment, extent of the consolidation, blood culture, initial white cell count, duration after the onset of treatment, associated diseases and complications. The mortality rate was 15.7 per cent for the entire sulfanilamide group and 30.8 per cent for the controls. The death rate for fifty-seven patients with types I, II, V, VII and VIII pneumonia treated with sulfanilamide was 10.5 per cent, whereas it was 27.5 per cent for forty patients with the same types treated with serum. Of twenty-one patients with pneumococcic bacteremia treated with sulfanilamide seven died, of twelve treated with serum six died and of fifteen controls thirteen died. The most important toxic manifestation was anemia. In 5.2 per cent of the patients treated with sulfanilamide a severe hemolytic anemia developed and in an additional 18.2 per cent moderate secondary anemia developed.

#### PNEUMOCOCCIC PNEUMONIAS COMPLICATING PREGNANCY AND THE PUERPERIUM

MAXWELL FINLAND, M.D.

BOSTON  
AND

THOMAS D. DUBLIN, M.D.

NEW YORK

It has long been recognized that pneumonia is a serious complication of pregnancy with a considerably higher death rate than for nonpregnant women.<sup>1</sup> Some of the factors pertaining to pregnancy have received limited attention in the past,<sup>2</sup> but data concerning the pneumonias are scarce. From the practical possibilities of reducing mortality, recent developments in the fields of specific serum therapy and of chemotherapy have focused attention on the etiologic agents in infectious diseases, and this has been true particularly in the case of the pneumonias. References to the bacterial incitants of the pneumonias of pregnancy are very scarce and, until the recent reports of Bullowa<sup>3</sup> and of Rogers and Gooch,<sup>4</sup> have been limited to individual case reports.

There is at present a widespread interest among physicians and public health workers in the control of the mortality from pneumonia. Much of this attention is focused on etiologic diagnosis, particularly pneumococcus typing, and on the specific serum treatment of some of the pneumococcic pneumonias. It is appropriate therefore to present a series of 212 cases of "typed" pneumococcic pneumonia complicating preg-

From the Thorndike Memorial Laboratory, Second and Fourth Medical Services (Harvard) Boston City Hospital and the Department of Medicine, Harvard Medical School.

Owing to lack of space this article has been abbreviated for publication in THE JOURNAL by the omission of tables 1, 3, 4, 7, 10 and 11. The complete article appears in the authors' reprints.

Dr. Alexander W. Winkler assisted in the collection of the data in the earlier part of this study and Dr. John W. Brown assisted with the more recent cases. Dr. Frederick C. Irving gave us permission to use the data from the Boston Lying-in Hospital, and Dr. K. Jefferson Thompson, former research fellow in obstetrics, carried out the serum treatment of a number of the patients there. The members of the staff of the obstetrics service of the Boston City Hospital cooperated.

nancy and the puerperium from the Boston City Hospital and the Boston Lying-in Hospital. The chief interest in this study concerns the classification of these cases according to the type of the pneumococcus and the influence of specific serum treatment on the mortality of the pneumonias due to some of these types. However, the effect on mortality of some of the other important factors concerning both the pneumonia and the pregnancy will be considered.

Only those patients have been included who had definite symptoms and physical and/or x-ray signs of pneumonia and from whose sputum, lung or pleural fluid or blood cultures pneumococci were identified and typed before July 1, 1938. About one third of the cases occurred before 1929, when typing was carried out only for types I, II and III. In almost all the remaining cases the pneumococci were classified with the aid of serums for the higher types.<sup>5</sup> Most of the serum treated patients received concentrated antipneumococcus horse serums. A few of the cases of type I pneumonia occurred between 1919 and 1922 and the patients were treated with unconcentrated type I antipneumococcus horse serum,<sup>6</sup> and in some of the recent cases homologous type-specific concentrated rabbit

serums were given.<sup>7</sup> Five patients were treated non-specifically with serums containing no antibodies for the homologous type of pneumococcus. These have been included among the non-serum treated patients. The pneumococcus typings were carried out by standard methods.<sup>8</sup> The Neufeld method<sup>9</sup> applied directly to sputum or to the peritoneal exudate of mice inoculated with sputum has been relied on for most of the rapid typing in the recent cases. At the Boston City Hospital, most of the prepartum pneumonia was treated in the medical services with the cooperation of the obstetrics staff. The postpartum pneumonias and those occurring late in pregnancy were usually treated in the obstetrics service with the cooperation of the staff of the medical services. Thirty of the cases are from the Boston Lying-in Hospital.

## INCIDENCE

Since bacteriologic studies of cases of pneumonia have been made as a routine in very few clinics, the available figures concern all the pneumonias irrespective of cause and there are scant reliable data concerning the incidence of pneumococcal pneumonias associated with pregnancy. Norris and Farley<sup>10</sup> collected 13,611 cases of pregnancy, among which pneumonia was diagnosed in 120, or 0.8 per cent. Jurgensen<sup>1</sup> reported pneumonia among 2.3 per cent of 1,842 pregnant women. Wessinger<sup>2</sup> quoted figures from Vienna indicating that forty-seven, or 1.9 per cent, of 2,475 women with pneumonia were pregnant. Nuckels and Hertig<sup>11</sup> found twenty-three women with pneumococcal infections (probably all had pneumonia) among 20,364 delivered at the Boston Lying-in Hospital, an incidence of one case to 855 deliveries. They stated the general belief that pneumococcal infections are less common in pregnant than in nonpregnant women because of the comparatively sheltered existence of the former. Rogers and Gooch,<sup>1</sup> on the other hand, found the pregnancy rate (where the duration of pregnancy is six months or more) to be 6.6 per cent for their serum treated women of child-bearing age with type I pneumonia, as compared to an estimated 2.1 per cent rate of pregnancy in a similar age group in the general female population.

The data concerning the incidence of pneumonia at the Boston City Hospital for the arbitrarily chosen period 1931-1937, inclusive, were reviewed (table 1). All patients admitted during pregnancy or the puerperium and all those for whom a diagnosis of pneumonia was made irrespective of cause were included. Among the 13,446 patients with pneumonia, 1,277, or 9.5 per cent, were between 18 and 45 years of age. These included 164 pregnant or recently parturient women, constituting 1.2 per cent of all those with pneumonia, or 12.8 per cent of the women with pneumonia who were between 18 and 45 years of age. Among the 25,891 patients admitted to the hospital in the same period during pregnancy or the puerperium, the incidence of all pneumonias was 0.63 per cent, or one case of pneumonia in 158 cases. It is interesting to note that while lobar pneumonia was more frequent than the atypical pneumonias (bronchopneumonias) in all women between 18 and 45 (12.4 and 7.5 per cent respectively) the reverse was true of the pneumonias complicating pregnancy. With women of this age group, 10.4 per cent of the cases of lobar pneumonia occurred in association with pregnancy, as compared with 15.7 per cent of the cases of bronchopneumonia. This is consistent with previous observations to the effect that lobar pneumonia is usually a primary disease and that the atypical pneumonias are more often secondary to other serious conditions except in infants and in aged persons.<sup>12</sup>

## CHARACTER OF THE PULMONARY LESIONS

Other features bearing on the character of the pulmonary lesions were brought out in an analysis of the cases of pneumococcal pneumonia under consideration, in 142 of which the condition occurred during preg-

10 Norris, G. W. and Farley, D. L. in Osler, William and McCrath, Thoma. *Modern Medicine*. Philadelphia: Lea & Febiger, 1913, vol. 1, p. 264.

12 Finland, Maxwell. The Significance of Specific Pneumococcus Types in Disease. Including Types IV to VIII (Cooper). *Ann. Int. Med.* 10: 1531 (April) 1937.

nancy and in seventy of which it began after delivery. In approximately one in every four cases of pneumonia occurring during pregnancy the pneumonia was "atypical" or bronchopneumonia, whereas in about one half of the cases of pneumonia observed post partum the condition was atypical. The mortality for the atypical pneumonias was higher in each instance, in spite of a lower incidence of bacteremia (table 2). This, again, is in accord with the observations previously recorded for all pneumococcal pneumonias.<sup>1-</sup>

#### TYPES OF PNEUMOCOCCI

The incidence of the various types among the 212 cases of pneumococcal pneumonia complicating pregnancy and the puerperium was similar to that found among 2,484 cases previously reported from the Boston City Hospital<sup>12</sup> (table 3). Type I was the most frequent type and accounted for about one fourth of the cases in each series. Among the other common types, types V and XIV had a somewhat higher incidence; type VII had the same incidence, and types II, III and VIII were somewhat less frequent in the cases of pneumonia complicating pregnancy. Since the mortality for the pneumonias caused by some of these types of pneumococci has been favorably influenced by treatment with type-specific antisera<sup>13</sup> it is of interest to note the results in the cases of pneumonia complicating pregnancy.

#### MORTALITY AND BACTEREMIC INCIDENCE

It is necessary first to consider the general mortality in the present cases in comparison with all cases of pneumococcal pneumonia. Since age and bacteremia are the two most important factors influencing mortality, their effect was analyzed. In each decade the death rate was found to be higher for pneumonia complicating pregnancy and the puerperium than for all the pneumonias. This higher death rate was constantly associated with a higher incidence of bacteremia (table 4).

#### EFFECT OF SPECIFIC SERUM TREATMENT ON MORTALITY

Serum treatment for types other than I and II was available during the last three years of the study and was used mostly for pneumonia due to types V and VII pneumococci. The mortality rates for the serum treated and non-serum treated patients are listed by type in table 5. The death rate for all the fifty-four patients treated with specific serum was 20 per cent as compared with 35 per cent for those who did not receive specific serum. These figures do not convey the complete picture, however, even when the bacteremic incidence is taken into account for it is necessary to consider the various factors contributing to the death in each of the fatal cases. Some of these factors in most of the cases from the Boston City Hospital have been noted in previous reports concerning serum therapy<sup>14</sup> and need not be reviewed here in detail. Briefly, in almost every one of the patients who died after specific treatment, one or more of the fol-

lowing conditions contributed to the failure of serum therapy: (1) delayed treatment, that is, treatment begun after the fifth day of the pneumonia, (2) grossly inadequate amounts of specific antibody, (3) treatment undertaken when the patient was in poor general condition, death occurring within a few hours, (4) mixed infections, notably hemolytic streptococcus sepsis, (5) focal complications, including vegetative endocarditis and (6) general systemic complications, such as decompensated heart disease or eclampsia.

It is of interest that Rogers and Gooch<sup>4</sup> had the same death rate, 19 per cent, for their forty-two serum treated pregnant patients with type I pneumonia, as compared with 11 per cent for serum treated nonpregnant patients aged from 15 to 45 with type I pneumonia. Bullock's<sup>4</sup> nineteen serum treated pregnant patients with type I pneumonia included six with bacteremia. There were five deaths, all associated with bacteremia. His entire series included fifty-nine patients with pneumococcal pneumonia complicating pregnancy, twenty-

\* Including patients treated with heterologous serum.

† Including one patient with type XIV pneumonia who died and one with type IX who recovered.

nine were serum treated with ten deaths (34 per cent), and thirty were not serum treated with seven deaths (23 per cent). However, there were seven bacteremic patients among the ten serum treated patients who died and only two among the seven non-serum treated patients, indicating that the patients with severest involvement were chosen for treatment with serum. In Ramsdell's<sup>1</sup> 352 collected cases of pneumonia in pregnancy (without respect to cause), there were ninety-six deaths or 27.3 per cent, as compared with a general mortality for pneumonia of 20 per cent.

#### COMPLICATIONS

Focal purulent complications were frequent among these patients, as may be expected from the high incidence of bacteremia.<sup>15</sup> They occurred in both the serum treated and the non-serum treated patients. Only the more common ones need be mentioned.

Empyema was the most frequent and occurred in ten serum treated and in fourteen non-serum treated patients, four of the former and eight of the latter died. This complication occurred predominantly with type I pneumonia: eight of the serum treated and five of the non-serum treated patients with empyema having

this type Subcutaneous pneumococcic abscess occurred in five of the bacteremic patients who recovered, three were serum treated and two were not Pneumococcic otitis media occurred in one serum treated and in three non-serum treated patients who recovered Hemolytic streptococcus sepsis, including pleural and puerperal infections, occurred in four of the serum treated and in seven of the non-serum treated patients, and only one of the latter recovered Endometritis with pneumococci cultured from the uterus or lochia occurred in the following five cases a fatal case of non-serum treated type I pneumonia with bacteremia following a forceps delivery, a case of serum treated type II pneumonia with bacteremia following normal delivery, with subcutaneous pneumococcic abscesses in addition, with recovery, a fatal case of non-serum treated type I pneumonia following cesarean section, a case of non-serum treated type XXIII pneumonia following cesarean section, and a fatal case of non-serum treated type II pneumonia following a septic induced abortion In addition, three non-serum treated patients had pneumococcic peritonitis limited mostly to the pelvis, these included

TABLE 6—Mortality of Pneumococcic Pneumonia in Relation to Duration of Pregnancy

	Number of Patients	Died	Percentage Died
First trimester	20	6	30
Second trimester	54	12	22
Before seventh month	74	18	24
Third trimester	51	24	47
At term	17	5	30
Seventh month and later	68	29	43
Post partum	70	20	29
Pre partum serum	38	8	21
no serum	104	39	38
Post partum serum	16	3	19
no serum	54	17	31

one patient with type II, one with type III and one with type V pneumonia In all cases the pneumonia followed an induced abortion The patient with type III survived, and the other two patients died One of the non-serum treated patients with type VIII died with meningitis, and a serum treated patient with type V died with rheumatic heart disease and vegetative endocarditis Lung abscesses occurred in four non-serum treated patients, two of whom died

#### EFFECT OF THE DURATION OF PREGNANCY ON MATERNAL MORTALITY

Death rates have usually been found to be higher for pneumonia occurring in the late months of pregnancy than for pneumonia occurring in the earlier months In Ramsdell's<sup>1</sup> cases there were thirty-two deaths (22 per cent) among 144 cases of pneumonia occurring in the first six months of pregnancy, as compared with fifty deaths (30.5 per cent) among the 164 cases of pneumonia occurring after the sixth month Harris<sup>16</sup> found a steadily increasing mortality up to 61 per cent in the last month of pregnancy for his collected cases of influenza with pneumonia Among Rogers and Gooch's<sup>4</sup> serum treated patients with type I there was one death among fourteen women less than six months pregnant (7.1 per cent), as compared with seven deaths among twenty-seven women who had been pregnant six months or longer (25.9 per cent) In the present series there are almost equal numbers of cases of postpartum pneumonia, cases of pneumonia complicating pregnancy

of six months' duration or less and cases of pneumonia complicating pregnancy of more than six months' duration The death rates in each of these groups are listed in table 6 The highest death rate was for the women in the third trimester of pregnancy The cases of pneumonia occurring at term or post partum have a somewhat lower mortality The serum treated patients had an appreciably lower death rate than the non-serum treated patients This was true for both the cases of prepartum and the cases of postpartum pneumonia This will be referred to again in relation to the interruption of pregnancy

#### PARITY AND MATERNAL MORTALITY

There were twelve deaths among forty-five primiparas (27 per cent) and fifty-three deaths among 165 multiparas (37 per cent) With the non-serum treated patients the death rate was appreciably lower for the primiparas than for the multiparas (26 and 38 per cent respectively) The death rate for forty-eight multiparous serum treated patients was 19 per cent, in contrast with a 38 per cent mortality for 117 similar non-serum treated patients There were two deaths among the six primiparous serum treated patients but one of these deaths was associated with eclampsia and the other with rheumatic heart disease and vegetative endocarditis In Ramsdell's<sup>1</sup> series there were eight deaths among eighty-nine multiparas (20 per cent) and four deaths among thirteen primiparas (31 per cent) The effect of age in the present series has already been noted (table 4) In Ramsdell's cases the death rate for patients under 25 was 13.3 per cent, for those from 25 to 35 it was 23.3 per cent and for those over 35 it was 22 per cent

#### TERMINATION OF PREGNANCY DURING THE PNEUMONIA

Pregnancy was terminated in more than one half of all the cases (55 per cent) (table 8) It was terminated more frequently in the fatal cases than in those of recovery, 70 per cent of the patients who died and 48 per cent of those who recovered aborting in the course of the infection Likewise, abortion was less frequent in the first six months of pregnancy (43 per cent) than after the sixth month (69 per cent) However, the lower incidence of abortions before the sixth month was limited to the cases of recovery The pregnancy was terminated in about one third of the women who were pregnant six months or less and recovered, whereas about two thirds of all the other patients were delivered The frequency of delivery was similar for the serum treated and the non-serum treated patients (table 9) In Ramsdell's cases 52 per cent of those in the first six months aborted, as compared with 70 per cent of those pregnant more than six months Of his patients who died, 85.4 per cent were delivered

#### EFFECT OF DELIVERY ON MATERNAL MORTALITY

In Ramsdell's cases there were seventy deaths among 190 patients with pneumonia who aborted, or 36.7 per cent, as compared with twelve deaths, or 10.7 per cent, among 118 patients who did not abort In Harris's<sup>16</sup> cases of influenza with pneumonia complicating pregnancy, there were 41 per cent of deaths among 383 cases in which pregnancy was uninterrupted as compared with 63 per cent of deaths among 395 cases in which pregnancy was ended In the present series (table 9) the lower death rate was limited to the women who were pregnant less than six months and were not delivered None of the nine serum treated patients in

<sup>16</sup> Harris J W Influenza Occurring in Pregnant Women J A M A 72 978 980 (April 5) 1919

this group died, and five, or 15 per cent, of the thirty-two non-serum treated patients died. For all the patients delivered and for those who were more than six months pregnant and were not delivered, the death rate was between 45 and 50 per cent without serum therapy and between 25 and 30 per cent with such therapy. The combined death rate for serum treated and non-serum treated patients was 22 per cent for the undelivered patients and 42 per cent for those who were delivered.

The termination of pregnancy took place at almost any time during the course of the pneumonia (table 10). About one half of the patients were delivered during the first five days of the disease. Among the forty-one patients delivered during the first five days of the pneumonia, nineteen, or 46 per cent, died, as compared with fourteen, or 39 per cent, among the thirty-six patients delivered after the fourth day. In Ramsdell's series 40 per cent of those who aborted before the third day died, as compared with 28 per cent of the sixty-nine who aborted after the third day.

#### RELATION OF SERUM TREATMENT, DELIVERY AND MATERNAL DEATHS

There were thirty-eight serum treated patients among those who had pneumonia before parturition. Of the sixteen who were not delivered, two died. Treatment with serum was begun before delivery with eleven patients, of whom two died, and serum was given to eight other patients after delivery and two of these patients died. In the three remaining cases, delivery took place on the day treatment was begun and two of the patients died after treatment.

#### DURATION OF THE PNEUMONIA

The number of days from the onset of the acute symptoms of pneumonia to death or to recovery by crisis or lysis was also analyzed (table 11). The numbers of cases are too few to indicate anything more than the trend. In the undelivered patients death

TABLE 8—Frequency of Delivery During Pneumococcic Pneumonia Complicating Pregnancy

Duration of Pregnancy	Recovered			Died			All Patients		
	Number of Patients	Delivered	Percentage Delivered	Number of Patients	Delivered	Percentage Delivered	Number of Patients	Delivered	Percentage Delivered
First three months	14	5	36	6	5	83	20	10	50
Second three months	42	14	33	12	8	67	54	22	41
Six months or less	56	19	34	18	13	72	74	32	43
Third three months	2	17	65	24	17	71	51	34	67
At term	12	10	83	0	3	60	17	13	76
Seven months or more	20	27	69	20	20	69	68	47	69
Total	90	46	48	47	33	70	142	79	55

tended to occur early, that is between the third and the sixth day, in those who were pregnant more than six months and was delayed until the seventh day or later in those who were in the first two trimesters of pregnancy. In the patients who were delivered, death occurred a week or more after the onset in most of the cases, except for about one third of those in late pregnancy, who died on or before the sixth day. Of the patients who recovered, crisis tended to occur somewhat earlier in the undelivered ones. Thus about two thirds of the undelivered patients had a crisis within seven days, while only one third of the delivered patients reached the crisis by the end of the seventh day.

#### RATE OF THE FETUS

Among the seventy-nine patients with pneumococcic pneumonia who were delivered during pregnancy thirty-one (39 per cent) had living babies, thirteen (16 per cent) had babies who died soon after birth and thirty-five (44 per cent) had stillbirths. Of the thirty-one mothers who were delivered of living babies nine (29 per cent) died, whereas about one half of the remaining mothers died. The death rate was about the same for those with stillbirths and for those whose babies died

TABLE 9—Maternal Mortality of Prepartum Pneumococcic Pneumonias in Relation to the Fate of Pregnancy

	Not Delivered			Delivered		
	Number of Patients	Number Died	Percentage Died	Number of Patients	Number Died	Percentage Delivered
Sixth month or before						
Serum treated	0	0	0	10	3	30
Non serum treated	33	6	15	22	10	46
Seventh month or later						
Serum treated	7	2	29	12	3	25
Non serum treated	14	7	50	35	17	49
All patients with prepartum pneumonia						
Serum treated	16	2	13	22	6	27
Non serum treated	47	12	26	57	27	47

soon after delivery. In almost all the cases the labor was very brief and in many it was followed by varying degrees of peripheral vascular collapse (shock).

As shown in table 12 there was no marked predominance of any particular type of delivery in the cases of postpartum pneumonia. In about one fourth of the cases the pneumonia occurred after cesarean section and in a similar number it followed abortion, either spontaneous or self induced. In the remaining cases the delivery was either entirely normal or some anesthesia (usually nitrous oxide, oxygen and ether) was used during a difficult labor or during the application of forceps. The maternal death rate was lowest for the women who were delivered spontaneously or who had a brief anesthesia during the application of forceps.

The fate of the fetus in the cases of postpartum pneumonia is also shown in table 12. In all the cases of abortion the abortion occurred before the seventh month, and only one of the sixteen babies lived for a short time after delivery. Of the fifty-four mothers who were delivered at term and later had pneumonia, forty-six had normal living babies and twelve (26 per cent) of the mothers died of the pneumonia. Four of the remaining eight mothers had stillbirths and the other four had babies who lived for a short time after delivery. One of the latter mothers died of her pneumonia.

#### TIME OF ONSET OF POSTPARTUM PNEUMONIA

In almost all of the cases of postpartum pneumonia the condition began within the first two weeks after delivery (table 13). In slightly more than one third of the cases, the pneumonia began on the second day post partum, and three fourths of all the patients had their initial symptom during the first three days post partum.

#### COMMENT

Pneumonia complicating pregnancy has a double interest. It concerns the obstetrician because of the high maternal and fetal mortality which it entails, and it concerns the internist because it carries with it a considerably higher death rate than pneumonia in nonpregnant women. It accounts for about one death in every

5,000 deliveries<sup>17</sup> and is the cause of about one half of the maternal deaths that are due to nonobstetric causes<sup>18</sup>. There can be little doubt that pneumonia complicating pregnancy warrants every possible consideration in an attempt to curtail the death rate. Now that effective specific serums are available for the large majority of the pneumococcal pneumonias, it is important to use the diagnostic procedures necessary for identification of the etiologic agent and to type the pneumococci as soon as the diagnosis of pneumonia is suspected. Early and adequate treatment with the homologous type-specific antipneumococcus serums can be expected to reduce materially the high death rate from the pneumonias when they complicate pregnancy, as demonstrated in the cases presented.

The dosage of serum in the treatment of pneumococcal pneumonia has been considered elsewhere.<sup>7</sup> The higher death rate and particularly the higher incidence of bacteremia in the cases of pneumonia complicating pregnancy are definite indications for larger doses than

of severe pneumococcal pneumonias, such as those considered here. Other derivatives, such as sulfapyridine, may prove to be very useful, but there are good reasons for the belief that the greatest benefits from these drugs in the treatment of pneumococcal pneumonias will be obtained from their use in conjunction with specific antipneumococcus serums. The pneumonias of pregnancy are sufficiently serious to warrant the use of every available means of treatment, and the proved efficacy of specific serum therapy warrants primary consideration in those cases in which it is applicable.

## SUMMARY

Data were studied concerning the incidence of pneumonia in pregnancy at the Boston City Hospital. About one of every eight women of child-bearing age who had pneumonia was pregnant, 0.63 per cent of all women admitted during pregnancy or parturition had pneumonia and in 1.2 per cent of all the cases of pneumonia the condition was complicated by pregnancy.

are used for nonpregnant patients. These larger doses have been recommended in the Massachusetts pneumonia control program<sup>19</sup> and were used in the present cases. As much as 1,400 cc of unconcentrated type I serum was given in some of the earlier cases in this series. The average dose in the recent cases was more than 250,000 units, which is higher than that used in other patients of the same age groups.

It is too soon to evaluate the place of chemotherapy in the treatment of pneumonia. There is no doubt that the use of sulfanilamide has materially reduced the death rate from hemolytic streptococcus infections, which are responsible for most puerperal sepsis. That this drug may favorably influence streptococcal pneumonia is to be anticipated, although there is no convincing evidence so far that it does. The drug is known to enter the fetal circulation and the mother's breast milk,<sup>20</sup> but its influence on the baby or the fetus has not yet been determined. There is no good evidence that sulfanilamide itself has curative value in the treatment

A series of 212 cases of typed pneumococcal pneumonia complicating pregnancy and the puerperium which occurred at the Boston City Hospital and the Boston Lying-in Hospital were analyzed with respect to the more important features concerning both the pneumonia and the pregnancy.

The incidence of pneumococcal types in these cases was similar to that found in all cases of pneumonia in adults. The types for which specific antipneumococcus serum has proved effective were the most frequent.

TABLE 13—*Interval Between Delivery and Onset of Postpartum Pneumonia*

Days	1	2	3	4	5	6	7	8	15	16+	Total
Number of cases	15	24	12	2	4	1	2	6	2	63	

Bacteremia was more frequent than in all cases for the same age groups and the death rates were higher than in corresponding cases for the same age group.

The death rates were highest for late pregnancy and for women whose pregnancy was terminated during the disease.

The death rate for all the serum treated patients was almost one half of that for the corresponding non-serum treated patients. The lower death rates were for pneumonia complicating both early and late pregnancy, for postpartum pneumonia, for women who were delivered and those whose pregnancy was unaffected.

The frequency with which pregnancy was terminated did not seem to be influenced by serum treatment.

# THE TREATMENT OF PNEUMOCOCCIC MENINGITIS WITH SULFANILAMIDE

REVIEW OF THE LITERATURE AND REPORT OF SIX ADDITIONAL CASES

BARBARA A. HEWELL, MD  
AND  
A. GRAEME MITCHELL, MD  
CINCINNATI

In a review of the literature to the year 1927 the Goldsteins<sup>1</sup> collected 150 authentic recoveries from pneumococcic meningitis and there are listed in the *Quarterly Cumulative Index Medicus* approximately thirty additional recoveries during the years 1927 to 1937. Most of these favorable outcomes have been attributed to spinal drainage and the administration of antipneumococcus serum or ethylhydrocupreine (optochin), but in general results with these therapeutic measures have been unsuccessful.

In the ten years preceding 1937 there were in the Children's Hospital of Cincinnati and in the pediatric service of the Cincinnati General Hospital twenty-three

## REPORT OF CASES

**CASE 1—Pneumococcic meningitis (type V) following otitis media and mastoiditis.** C. M., aged 9 years, had had otitis media with drainage from the right ear for five days and meningeal signs for twenty-four hours. Antimeniugococcus serum was given intraspinally prior to admission. Cultures of material from the ears and of the spinal fluid were positive for pneumococcus type V and of material from the mastoid region were negative. Roentgenograms of the mastoid regions showed cloudiness of the cells on the right, at operation pus was found in the right mastoid region. Blood cultures on the first and second days were negative. Cultures of the spinal fluid were negative on the third day and thereafter. The clinical course was mild. The patient received a total of 27 Gm of sulfanilamide by mouth and an equal amount of sodium bicarbonate, ethylhydrocupreine hydrochloride (27 Gm) was also given. There were no toxic effects. Recovery was complete.

**CASE 2—Pneumococcic meningitis (type III) following otitis media and mastoiditis.** A. M., aged 10 years, had had bilateral otitis media for one week and headache, drowsiness and stiffness of the neck for twelve hours. Cultures of material from the ears showed an intermediate type of streptococcus, of material from the mastoid region a hemolytic *Streptococcus aureus* and of the spinal fluid pneumococcus type III. Roentgenograms of the mastoid regions showed cloudiness of the cells on the left at operation pus and sclerotic cells were found in the left

Chart 1—Observations in case 1

Chart 2—Observations in case 2

Chart 3—Observations in case 3

children suffering from pneumococcic meningitis, the mortality in this group being 100 per cent. Since the use of sulfanilamide three patients with the condition have recovered of a total of six treated. The histories of these six patients are summarized.

In table 1 are listed thirty cases of recovery from pneumococcic meningitis in which the treatment consisted in part of the administration of sulfanilamide or related compounds.

In table 2 are listed the reports of eight cases of pneumococcic meningitis treated with sulfanilamide or related compounds in which death occurred.

mastoid region. Four blood cultures were negative. Cultures of the spinal fluid were negative on the fourth day and thereafter. The patient received a total of 24 Gm of sulfanilamide and an equal amount of sodium bicarbonate by mouth and small amounts of 0.8 per cent sulfanilamide intraspinally and intravenously daily for seven days, ethylhydrocupreine hydrochloride (0.7 Gm) was also given. There were no toxic effects. Recovery was complete.

**CASE 3—Pneumococcic meningitis (type III) following otitis media and mastoiditis.** M. T., aged 8 years, had had bilateral otitis media one month before, but recovery was apparently complete. On admission the complaints were chill, frontal headache and photophobia. There was bilateral bulging of the ear drums. Cultures of material from the ears after myringotomy showed *Staphylococcus aureus*, of material from the mastoid regions an unidentified diphtheroid and of the spinal fluid pneumococcus type III. Roentgenograms of the mastoid regions showed slight clouding of the cells on both sides more

From the Children's Hospital Research Foundation and the Department of Pediatrics, University of Cincinnati College of Medicine.  
1. Goldstein H. I. and Goldstein H. Z. Pneumococcus Meningitis and Endocarditis. Report of Twenty Cases of Pneumococcus Meningitis With and Without Pneumococcus Endocarditis. Consideration of Treatment and Review of Literature. Internat. Clin. 3: 155-219 (Sept.) 1927.

marked on the left, at operation pus was found in both mastoid regions. Blood cultures on the first, twelfth and eighteenth days were negative. Cultures of the spinal fluid were negative on the third day. Some clinical improvement was noted at this time. On the twelfth day slight dyspnea developed and the heart was markedly enlarged, as demonstrated by physical examination and roentgenogram. The patient became worse on the sixteenth and seventeenth days, when there was increased pressure of the spinal fluid and when also the spinal fluid cultures were again positive. There were no localizing signs of brain abscess until the eighteenth day, when a definite left homonymous hemianopia and weakness of the left arm and left leg were present. Trepanation was performed and burr holes

made in the skull, 16 cc of pus was aspirated from the right temporal region. Ventricular and lumbar punctures were performed every eight hours from the nineteenth to the twenty-first day. There was slow improvement. The patient received a total of 64 Gm of sulfanilamide with an equal amount of sodium bicarbonate, ethylhydrocupreine hydrochloride (16 Gm) was also given. Recovery was complete.

CASE 4—*Pneumococcus meningitis (type III) following otitis media and mastoiditis*. W. L., aged 9 years, had had bilateral otitis media with a high fever for one week and swelling in front of the right ear for two days. Cultures of material from the ears showed *Staphylococcus albus*, from the right mastoid no growth and from the left mastoid a gram positive spore

bearing rod. Cultures of the spinal fluid were positive for *Streptococcus viridans* until the tenth day at which time pneumococcus type III was observed. Spinal fluid cultures remained positive for pneumococci throughout despite a fall in the cell count. Roentgenograms of the mastoid regions showed haziness of the cells on the right, at operation pus was found in both mastoid regions. The patient became increasingly drowsy and was comatose for forty-eight hours before death on the seventeenth hospital day. Necropsy showed purulent meningitis with no evidence of sinus thrombosis or brain abscess. The patient received a total of 64 Gm of sulfanilamide with an equal amount of sodium bicarbonate by mouth, a small amount of 0.8 per cent sulfanilamide intraspinally on eight occasions and prontosil intravenously (20 cc on three occasions).

CASE 5—*Pneumococcus meningitis (type III) following otitis media and mastoiditis*. M Y, aged 7 years, had had bilateral otitis media for two weeks, frontal headache for five days and

stiffness of the neck for three days. On admission there was slight stiffness of the neck, Brudzinski's sign and photophobia were present, the reactions of the pupils to light were sluggish, there were bilateral nystagmus and bilateral papilledema, the deep reflexes were hypo active and there was dulness of the ear drums. Cultures of material from the right ear after myringotomy were positive for pneumococcus type III and from the left ear were negative. Roentgenograms of the mastoid regions were negative on two occasions. Trepanation was performed on the third day as a safeguard for lumbar punctures. A blood culture on the second day was positive for pneumococcus type III. Spinal fluid cultures were negative until the fifth day, when pneumococcus type III was found. Bilateral mastoidectomy was performed on the sixth day, on the right there were necrotic cells and pus, and on the left the cells were apparently normal. Cultures of material from the mastoid regions were negative. There was no clinical improvement. No localizing signs of brain abscess were present. The pres-

sure of the spinal fluid increased. Ventricular punctures and aspiration for brain abscess were performed on the tenth day. 10 cc of pus was obtained through burr holes made in the right cerebellar region and no abscess cavity was found. Icterus developed on the sixth day, and the patient died on

the twelfth hospital day. Necropsy showed extensive destruction of the mastoid bone, epidural pus over the cerebellar hemisphere, extensive cerebral leptomeningitis, abscess of the left occipital lobe (small and early), thrombosis of all the meningeal sinuses and early lobar pneumonia. The patient received 36 Gm of sulfanilamide with an equal amount of sodium bicarbonate by mouth and small amounts of 0.8 per cent sulfanilamide intraspinally and intravenously on six occasions.

**CASE 6—Pneumococcal meningitis (type VII).** H C, a white girl aged 2 months was seen only casually by us and only a brief history is possible. She had had fever and been irritable for one week and had a convulsion on the day of admission. The fontanel was bulging, the ear drums were slightly dull, there was stiffness of the neck and Brudzinski's sign was present. The patient was in coma on admission. The spinal fluid showed 22,400 cells, a positive Pandy reaction and pneumococcus type VII. The blood culture was positive for pneumococcus type VII. The patient received a total of only 6 Gm of sulfanilamide. She also received ethyl hydrocupreine hydrochloride in rather large doses and specific serum intramuscularly. She died on the sixth day after admission.

#### SUMMARY

There are at least thirty reported cases of recovery from pneumococcal meningitis, including three observed by us, in which part of the treatment consisted in the use of sulfanilamide or related compounds. It appears reasonable to conclude that sulfanilamide compounds were responsible for these recoveries in most instances since the mortality

2 This is not a complete list since a few reports were not available to us.

rate was so high with other forms of treatment. In a few instances the dose was so small that the effect of the drug must be considered doubtful. It is to be noted that recovery occurred with the use of different compounds, such as prontosil, sulfanilamide and sulfapyridine, that is to say, the data now available do not permit conclusions concerning the relative merit of these different compounds in the treatment of pneumococcal meningitis.

There are at least eight cases of pneumococcal meningitis, including three observed by us, in which sulfanilamide was given and in which recovery did not follow.

It could not be shown statistically that the age of the patient, the dose of sulfanilamide employed or the type of pneumococcus had any relation to recovery.

Of the patients receiving sulfanilamide who recovered, only one showed pneumococci in the blood culture; sixteen other patients had negative blood cultures, and for thirteen cultures were not reported. Of the eight patients receiving sulfanilamide who died, the blood cultures were positive for seven. This indicates that even with the use of sulfanilamide a blood stream infection with pneumococci is a factor in mortality and perhaps also that with such infection large doses of sulfanilamide should be tried.<sup>3</sup>

## TREATMENT OF TESTICULAR DEFICIENCY WITH TESTOSTERONE PROPIONATE

E. PERRY McCULLAGH, M.D.  
CLEVELAND

Testicular function is known to be intimately connected with the growth of the penis and its erectile power, the growth and maintenance of the secondary sex glands, the maturation of the skeleton and the growth, and in some species the maintenance, of the secondary sexual characteristics. Chemical substances which have pharmacologic properties similar to those of testicular extracts have been isolated from human urine and animal adrenals, and they have been demonstrated in other tissues. Such substances are called androgens. Many androgens, some of which are known to occur in nature, have been produced artificially from sterols. Koch<sup>1</sup> has recently published a comprehensive review of the literature dealing with these facts.

Moore's<sup>2</sup> experiments showed that testis extracts produced evidence of damage to spermatogenesis, and he stated that testis hormones could not be used clinically without probable harm to the production of sperm. Walsh, Cuyler and McCullagh<sup>3</sup> in 1933 demonstrated that androgenic urinary extracts maintained spermatogenesis in hypophysectomized rats. More

recently this has been confirmed in the laboratories of the Cleveland Clinic and also by Nelson and Gallagher.<sup>4</sup> Although they appear to be opposed, both of these observations seem to be factual. Their clinical significance has not yet been made clear.

Fig. 3—Excretion curve of a castrate aged 48

The only androgen which has been isolated from testes is testosterone,<sup>5</sup> although it has not been proved that this is the only hormone of the testes or that it will completely replace the endocrine activity of that gland.

This study is concerned with the urinary excretion of androgens in the normal male, in cases of testicular deficiency and after injections of androgens. The data indicate in some degree to what extent testosterone propionate will develop and maintain the sexual organs and characteristics in the human male.

In the cases studied, particular attention has been paid to penile growth and function, the production of secondary sex characteristics, prostatic growth, production of semen, spermatogenesis, epiphyseal closure and the rate of urinary excretion of injected androgens. Since only persons with definite evidence of hypogonadism have been treated, many of the patients have been impotent and it has been impossible to study the production of semen until after therapy has been instituted. For similar reasons the data regarding production of sperm are scanty.

### BIO-ASSAYS FOR URINARY ANDROGENS

The most useful method of studying the hormonal activity of the testis is bio-assay based on capon comb growth. A highly accurate method and the one used in these studies is a modification of the one devised by Gallagher and Koch.<sup>6</sup> Brown or white leghorn capons may be used. After the urine to be extracted has been hydrolyzed by boiling with hydrochloric acid, it is extracted in a special apparatus by having benzene passed through it at a rate of from 6 to 8 liters an hour for two hours. Subsequently the benzene is distilled off, the acid neutralized and the extract dissolved in oil. The oil is injected into the breasts of five capons, and their comb growth forms the basis for computation. At the same time, for the purpose of comparison, a group of controls are given injections of standard amounts of crystalline androsterone. It has been shown

<sup>3</sup> Since this paper was submitted we have observed another patient with pneumococcal meningitis to whom both sulfanilamide and sulfapyridine were administered. Recovery followed within a period of about three weeks. Thus we have now treated seven patients with sulfanilamide or related compounds of whom four have recovered.

From the Cleveland Clinic.  
Mr. W. Kenneth Cuyler conducted all the assays reported in this paper.

Read before the Section on Urology at the Eighty-Ninth Annual Session of the American Medical Association, San Francisco, June 15, 1938.

Owing to lack of space this article has been abbreviated for publication in THE JOURNAL. The complete article appears in the author's reprints.

recently by D Roy McCullagh and McLin<sup>7</sup> that dibutyl ether is an excellent extracting solvent for androgenic substances and may be utilized with less complex equipment than benzene. Essentially the same results are obtained with the two methods.

#### NORMAL EXCRETION OF ANDROGENS

Normal levels of excretion of androgens are shown in table 1. The wide range of normal values both for different persons and for the same person is apparent.

The urinary excretion of androgens in normal men has been reported by Koch.<sup>8</sup> In twenty assays on men between 24 and 34 years of age the average number of bird units was 30, the lowest 16 and the highest 72.

The figures in table 2 demonstrate the range of androgen excretion of persons with distinct clinical evidence of hypogonadism as compared with that for normal persons. Such an assay as the one which yielded 16 units of androgens in the twenty-four hour urine of a castrate is interesting. It demonstrates clearly that not all androgens arise in the testes.

#### THE EXCRETION OF INJECTED ANDROGENS

The injection of testosterone propionate is followed by an increased excretion of androgens in the urine. By the use of available methods, however, it is not possible to determine what chemical substance is excreted. Such studies indicate in a general way the

frequency with which injections must be given and the doses necessary to maintain normal androgen excretion. If doses of 10 mg of testosterone propionate are injected, urinary androgens may fall to their original low levels within about three days. For example, a castrate 64 years old had had four preliminary assays, none of which showed any measurable androgen. He

was given 10 mg of testosterone propionate as Oreton,<sup>9</sup> and twenty-four hour specimens of urine were collected, beginning from the moment of injection. The first day 16 international units was excreted, the second day 2 and the third day none. A 33 year old patient with severe hypogonadism without treatment excreted 2

units in twenty-four hours. On three days following the injection of 10 mg of testosterone propionate he excreted 11, 7 and 2 units respectively.

If large doses are injected, the complete excretion apparently takes a longer time. A man 27 years of age had severe hypogonadism and had excreted 6.6 and 7 units of androgen per twenty-four hours before therapy. Assays indicated the excretion of 100 mg of testosterone propionate within six days.<sup>10</sup>

It is instructive to note the amounts of testosterone which must be injected in cases of hypogonadism to bring the urinary excretion to within normal range. Such doses as produce normal excretion have in the patients treated been adequate to overcome most of the evidences of testicular deficiency, symptoms have disappeared in a few days, anatomic changes requiring weeks or, in the case of severe prepuberal hypogonadism, many months. It has not been shown definitely that it is necessary to keep the urinary excretion normal in order to obtain desirable clinical effects. A male castrate 48 years of age without treatment repeatedly excreted quantities of androgens at about the lower range of normal. Figure 3 shows the consistent elevation in levels of urinary androgens with increasing doses of testosterone propionate.

#### RESULTS OF THERAPY FOR SEVERE PREPUBERAL TESTICULAR DEFICIENCY

Koch<sup>8</sup> has cited the results of Kenyon in the treatment of hypogonadism with synthetic androgens, and Hamilton<sup>10</sup> has reported the production of penile erections by the use of such androgens.

The most severe clinical test of the value of testicular hormone is the test of its ability to produce the ex-

<sup>9</sup> Oreton is the trade name of a solution of testosterone propionate in oil produced by the Schering Corporation and supplied for these studies through the courtesy of Dr. Irwin Schwenk and Dr. Max Gilbert.

<sup>10</sup> This work is being reported in greater detail in *Endocrinology* (to be published).

dences of normal function of testis hormone in persons who have had severe hypogonadism from before puberty to well into adult years. Six cases of such hypogonadism have been selected for this report, together with one case illustrative of what I believe to be functional hypogonadism and one case illustrating the effect of testicular hormone in an adult castrate. All of the patients with prepubertal hypogonadism received gonadotropic hormone therapy for several months with pregnancy urine extracts, pituitary extracts or a combination of these. In these cases the effect of the gonadotropic substances ranged from no observed change to mild symptomatic and very slight anatomic changes. In other instances such therapy has produced good results, and it is possible that larger doses might have been followed by better results in some of these cases, depending on the amount of reactive testis tissue present. In all instances, when testosterone propionate therapy was begun it was the only androgenic substance used. Thyroid therapy was used in two cases (3 and 5). Two of the cases are reported in some detail and illustrate well the type of change seen in the others, the more important data of which are reported.

CASE 1 (fig 4)—A man aged 23 complained in 1934 of lack of normal development. At the age of 15 because of cryptorchidism and pain, bilateral orchiopexy had been attempted, after which both testes atrophied. He had been less active

Fig 4—Patient 1 at 23 years and at 27 years. The development, including an increase in maturity of the facial expression, an increase in the breadth of the shoulders and development of the genitalia is apparent. This patient had received 3,220 mg. of testosterone propionate in the fifteen months before the second photograph was taken.

than the average youth. The sexual libido was minimal, masturbation, however, was practiced about monthly, apparently with orgasm but no ejaculate. The teeth had been well formed, but some cavities developed. He had grown 3 inches (7.6 cm) in height between the ages of 20 and 23 years.

Examination showed a person with the facial expression of a boy of 14 years. His voice was puerile. He was slender, with

long hands and feet. His height was 65¾ inches (167 cm) and his weight was 107 pounds (48 Kg). His span (both arms extended) was 70½ inches (179 cm) and the symphyseal height was 36¼ inches (92 cm). The skin was normal in texture, and the trunk and limbs were almost hairless except for about fifteen pubic hairs. The penis was preadolescent in type, measuring less than 4 cm from as close as the finger could be

Fig 5 (case 1)—A shows an epiphysal age of 16 years, the chronologic age being 23 years. B, chronologic age 27 years, after marked pubertal changes following treatment, the epiphysal maturity is unchanged.

pressed to the pubis to the end of the prepuce. The prostate was minute and flat, and it was questionable whether its borders could be defined by palpation. The small, pale scrotum contained two very soft pea-sized testes.

During 1934 and 1935, seven assays showed measurable traces of urinary androgens. No gonadotropic substance was demonstrated in the urine by the modified Friedman test. Six metabolism tests in 1934 and 1935 averaged —9 per cent. Blood counts, apart from showing a slightly low red cell count gave

TABLE 3—Therapy in Case 1

1935	July to January 1936	Prephysin	1 cc, 6 doses a week
1936	January to March	Prephysin plus antuitrin S	1 cc } 6 doses
			0.25 cc } a week
	March 18 to May 6	Androsterone	2.5 mg, every 2d day
	May 8 to November 30	Testosterone (plain)	2.5 mg daily
	December 16 to Feb 10 1937	Testosterone propionate	5 mg 3 times weekly
1937	Feb 10 to April	Testosterone propionate	10 mg 3 times weekly
	August to May 17 1938	Testosterone propionate	20 mg 3 times weekly

normal results. Urinalyses and examination of the blood sugar and blood cholesterol gave normal results. A trace of creatine was excreted on one of four occasions. The creatinine excretion was normal.

The sella turcica was normal to roentgen examination. The skeletal age estimated from the development of the epiphyses was just over 16 years.

The therapy is shown in table 3. The total dose of testosterone has been 3,715 mg.

While gonadotropic substance was being administered, repeated assays failed to show any rise in the level of excreted androgens and no symptomatic or anatomic change was noted. After the patient had received testosterone until August 1936 there were some penile growth (6 cm) and a questionable increase in the axillary and pubic hair, and erections were more frequent. This therapy also failed to raise the level of excreted androgens.

Immediately after the institution of testosterone propionate therapy, a twenty-four hour excretion of 28 units of androgen was found. Erections occurred daily or oftener. By February 10 a small ejaculate had occurred. With 10 mg every second day, 26 and 27 units of androgen were excreted. By

April the penis was 8 cm in length, the prostate was enlarging and the scrotum was more pendulous. In July nocturnal emissions began to appear about every three weeks.

The voice became decidedly deeper, and the appearance and demeanor were more mature. The patient has continued to grow in height, and the shoulders are broader. His present height is 69 inches (175 cm), his span 75 inches (190 cm), his symphysial height 38 inches (96 cm) and his weight 133 pounds (60 Kg). A light beard has appeared, and a puberal type of facial acne is present. The axillary hair is still sparse. The pubic hair approaches the normal amount, and there is obvious hair on the arms and legs. The penis is 10 cm in length and the scrotum larger, thicker and darker. The testes have not enlarged. The prostate is about 3 cm in width and from 2 to 3 cm in height. Erections and nocturnal emissions

Fig. 6—Patient 2 Dec 24 1936 and April 16 1938. He had received 3 560 mg of testosterone propionate in the intervening sixteen months.

occur normally. The ejaculate contains no sperm, is highly mucoid and has a volume of 15 cc. The blood count is unchanged; the blood sugar, calcium and phosphorus levels remain normal and unchanged, and the blood cholesterol content is 120 mg per hundred cubic centimeters. The basal metabolic rate is -9 and -13 per cent. An extremely interesting feature is that the epiphysal development has remained unchanged; the epiphysal lines, for instance at the lower end of the radius and ulna and at the proximal end of the first metacarpal, are as widely open as in 1934 (fig 5). This demonstrates that testosterone propionate, capable of producing most of the evidences of puberty, is alone not the substance which causes epiphysal closure, ordinarily considered an integral part of puberal maturity, or that larger doses are required to affect this function. It should be noted that the patient received no thyroid therapy.

CASE 2 (fig 6)—A white man aged 30 who complained Dec 19 1936, of failure of genital development had had mumps at the age of 8 years. His appearance was typical of eunuchism; his height was 68½ inches (174 cm) and his span

was 75½ inches (192 cm). The voice was high, there was a slight down on the cheeks and the axillary and pubic hair was very scant. The penis and prostate were infantile, and pea-sized testes were palpable. Erections occurred at about monthly intervals. There were no clinical evidences otherwise of pituitary or thyroid disease.

He had mild microcytic anemia. The basal metabolic rate was -21 per cent, and the blood cholesterol content was 190 mg per hundred cubic centimeters. Examination of the visual fields and roentgen examination of the sella turcica gave normal results. The epiphyses at the lower end of the radius and ulna and the crest of the ilium were incompletely closed. There was well developed hypertrophy of the radial epiphysis (the patient was a sign painter).

The Friedman test showed no evidence of gonadotropic substance. A urinary androgen content as high as 23 units per twenty-four hours was found before treatment. Between Feb 6 and April 10, 1937, he was given 6,200 units of gonadotropic substance. February 27 the urinary androgen content was 21 units. There was slight increase in testicular size and some improvement in the sense of well being.

April 10 the administration of testosterone propionate 10 mg every second day was begun. This was increased to 20 mg every second day August 1 and to 30 mg at the same intervals August 21 and has been 25 mg three times weekly since November 1937. The total dose of testosterone propionate has been approximately 3,900 mg.

When this therapy was begun, erections occurred promptly and appeared three or four times daily. In August the first nocturnal emission occurred, the voice was lower, the scrotum was more pendulous and the prostate was distinctly larger. In September facial acne appeared. The urinary androgen content was 74 units in August, 64 units in October and 40 units in March 1938.

Semen specimens measured 0.8 cc in August 1937, 27 cc in February 1938 and 17 cc in April 1938. There were no sperms.

By April 1938 the facial appearance was more mature, the beard had increased visibly, requiring shaving every third day, the body hair had increased considerably and the axillary and pubic hair approached normal. The voice had become much lower. The shoulder breadth appeared to have increased. The penis was 8 cm in length and erections were occurring several times a day and nocturnal emissions every few weeks. The prostate had grown to a size approximating normal for the age of 18 or 19 years, the median sulcus still being well marked. The testes were distinctly smaller than at the end of the gonadotropic substance therapy.

In May the basal metabolic rate was -5 per cent. The epiphysal line at the end of the ulna was closed and that of the radius appeared to be closed but the line could be distinctly seen. The epiphysis of the iliac crest was still ununited. It would appear that in this case the rate of epiphysal closure was hastened somewhat during therapy.

CASE 3 (fig 7)—A man aged 27 who in May 1936 complained of arrested sexual development was rather obese and showed all the evidences of severe prepuberal hypogonadism. There was no history suggestive of testicular injury. He had the appearance of a boy of 16. His height was 67½ inches (171 cm) and his span 71¾ inches (182 cm). He weighed 156 pounds (71 Kg). The voice was high. There were a few pubic and axillary hairs but no beard. The penis was 1 inch (2.5 cm) in length and the small scrotum held no palpable testes. The prostate was not palpable.

The sella turcica was normal to roentgen examination and the visual fields and dextrose tolerance were normal. There was slight microcytic anemia. The blood cholesterol content varied between 128 and 150 mg per hundred cubic centimeters. Four basal metabolic rates averaged -10 per cent. The epiphysal age was approximately 18½ years, the phalangeal epiphyses being closed. The Friedman test gave a negative reaction, and the urinary androgens measured 6 international units in twenty-four hours.

In 1934 three basal metabolic rates had averaged -5 per cent and the blood cholesterol content was 126 mg per hundred cubic centimeters. At that time the epiphysal lines of the

phalanges were incompletely closed. The bone age had been estimated to be  $16\frac{1}{2}$  years by Dr T W Todd and a diagnosis of hypothyroidism arrived at from roentgen evidence alone.

From October 1934 to August 1935 the patient had received 100 units of gonadotropic substance three times weekly with no benefit. Thyroid in varying doses was used from January to August 1935. The therapy since June 1936 is outlined in table 4. The total dose of testosterone propionate has been 5260 mg in seventeen months.

Fig 7—Patient 3 May 14 1936 and May 4 1938. He had received testosterone propionate for sixteen months before the second photograph was taken.

While the patient was taking androsterone and testosterone, the urinary androgen content varied from 3 to 4 units and erections increased slightly. A slight glairy secretion was seen at the urethral meatus, and the only anatomic change noted was slight penile growth.

TABLE 4—Therapy from June 1936 in Case 3

1936	June 12 to Aug 1	Androsterone 2 mg every second day
	Aug. 19 to Nov 2	Testosterone 2 mg every second day
	Nov 26 to Dec 16	Testosterone 3 mg every second day
	Dec 17 to Jan 9 1937	Testosterone propionate 3 mg 6 doses a week
1937	January 11	Testosterone propionate 10 mg 6 doses a week
	February 11	Testosterone propionate 10 mg 3 doses a week
	May 2 to May 24	No therapy
	May 24 to July 27	Testosterone propionate 10 mg 3 doses a week
	July 27 to Aug 18	No therapy
	Aug 18 to Oct 18	Testosterone propionate 20 mg 3 doses a week
1938	Oct 18 to May 1938	Testosterone propionate 30 mg 3 doses a week

With the patient receiving testosterone propionate, an androgen assay in December 1936 showed 21 units. By January 1937 assays showed a content as high as 119 units. Erections occurred three or four times daily. A small ejaculate was present. The penis had increased to 3 inches (7.6 cm) in length, and axillary and pubic hair had increased. When treatment was discontinued, the number of erections and the amount of ejaculate diminished markedly within ten days.

By April the ejaculate had increased further, axillary and pubic hair were increasing visibly, the scrotum was larger and darker and the penis measured  $3\frac{1}{2}$  inches (9 cm) from pubis to tip of prepuce. In August the voice was decidedly lower.

In October 1937 the ejaculate measured 0.4 cc. In November 1937, 0.8 cc, and in January 1938 0.5 cc. Nocturnal emissions occurred every two or three weeks. The results of blood

counts, the serum calcium, phosphorus and cholesterol contents and the metabolic rates have not changed. In May 1938 the epiphyseal age had advanced to 21 years. The epiphyseal development has therefore advanced at about a normal rate during the past four years but has apparently not exceeded the normal rate in spite of the large doses of testis hormone given. The testes have not become palpable.

At the present time axillary and pubic hair approach normal. The beard has increased slightly, and hair is appearing on the arms and legs. The voice is decidedly lower. The penis is  $3\frac{1}{4}$  inches (9.5 cm) long. The prostate has increased little if at all in size.

CASE 4 (fig 8)—A man aged 31 who in May complained of underdeveloped genitalia had no history suggesting testicular damage. The libido was minimal, there were no nocturnal emissions and erections were rare.

TABLE 5—Therapy in Case 4

Date	Medication	Assay
1936	May 12 to June 10	Testosterone 2 mg 3 times a week
	June 16	Dihydroandrosterone 25 mg 3 times a week
	July 20	Testosterone 2 mg 3 times a week
	October 6	Testosterone 3 mg 3 times a week
	November 1	
	November 15	
	December 1	Testosterone propionate 3 mg daily
	December 16	
1937	January	
	April	
	September 21	Testosterone propionate 10 mg daily
	December 6	

At the age of 20 years his height was  $65\frac{1}{2}$  inches (166 cm), and at the time of my examination ten years later it was  $67\frac{1}{4}$  inches (171 cm). The weight was 162 pounds (73 Kg), the span  $71\frac{1}{2}$  inches (182 cm) and the symphyseal height 36 inches

Fig 8—Patient 4 Dec 7 1936 and March 28 1938. He had received 2845 mg of testosterone propionate in the fifteen months before the second photograph was taken.

(91 cm). The voice was high and the face and body were hairless, but there was sparse axillary and pubic hair. The penis was very small, appearing 1 inch in length though actually it was  $2\frac{1}{4}$  inches (5.7 cm) when measured by pressing the rule against the pubis. The prostate was minute. The scrotum was very small, and the testes were the size of small peas.

The basal metabolic rate was  $-27$  per cent, but there were no clinical evidences of hypothyroidism. The blood cholesterol content was 176 mg per hundred cubic centimeters and later varied between 120 and 145 mg on several occasions. The epiphyseal age was 20 years. Assays for urinary androgens showed none. Roentgen examination of the sella turcica had given normal results repeatedly, and the visual fields showed no evidence of suprasellar lesions.

Treatment previously had included from 1 to 2 cc of gonadotropic substance in the form of antuitrin-S three times weekly for five months, with slight improvement. The treatment with testis hormones is outlined in table 5. The total dose of testosterone propionate was 2,845 mg in seventeen months.

Within a few days of the beginning of therapy erections increased, and by July they were occurring several times daily. In October 1936 the penis had increased  $2\frac{1}{4}$  inches (7.3 cm) in length and there was a slight viscid secretion at the meatus. In January 1937 facial acne of the puberal type was present, the voice had become decidedly lower and there was distinct though slight increase in the beard. The prostate was palpably larger but still smaller than normal. The penis measured  $3\frac{3}{4}$  inches (9.9 cm) in length and coitus was normal. The rate of progress was obviously faster with testosterone propionate than with other types of treatment used.

Cessation of injections for two and one-half weeks led to disappearance of the facial acne, lessening of the libido and potency and a slight decrease in the number of erections. By March 1938 the voice was distinctly low, the beard had increased visibly and the axillary and pubic hair were about normal. The scrotum was still small. The penis had increased to  $4\frac{1}{4}$  inches (10.8 cm) from pubis to tip. Frequent erections persisted. The prostate measured about  $1\frac{1}{2}$  by  $\frac{3}{4}$  inches (3.8 by 1.9 cm) as judged by palpation. The testes were unchanged in size. The epiphyseal age had just reached 21 years. The ejaculate was sperm free and had a volume of 4 cc.

#### THE QUESTION OF FUNCTIONAL HYPOGONADISM IN THE ADULT MALE (MALE CLIMACTERIC)

It is clear that testicular deficiency of severe degree does not always cause many symptoms, since some castrates have mild complaints. Impotence in itself cannot be considered evidence of hypogonadism, since in some of the cases studied high levels of urinary androgens have been found and large doses of testosterone propionate have not relieved the condition. In addition, a very low androgen content may be associated with general ill health with or without impotence. Arterial hypertension, for example, may be associated with a very low content, and even though this is raised to the normal range the associated excitability, irritability and impotence may remain unchanged. In some adult males, however, there may be symptoms suggestive of hypogonadism, a low androgen content being associated or unassociated with testis atrophy, and the use of testosterone propionate alone may be followed by complete symptomatic relief. The following is an example of such a case.

**CASE 7**—A man aged 58, first seen in February 1934 complaining of irritability, excitability and melancholia, was almost completely impotent. There was slight diffuse thyroid enlargement. The blood pressure was 110 systolic and 70 diastolic. The prostate was mildly enlarged. The testes were rather small, quite soft and associated with bilateral hydrocele. Blood counts, Wassermann tests and the sugar and cholesterol values were normal on repeated examinations. Four basal metabolic rates ranged from  $+5$  to  $-12$  per cent. A positive Friedman reaction was found on three of eight occasions. In August 1936 there were no urinary androgens and in October the content was 3 units. Throughout 1934 and 1935, treatment including the use of desiccated testis tissue and injections of hembreol, a urinary androgenic extract, did not improve his symptoms. From December 1935 to December 1936 mild improvement was noted while he was using dihydroandrosterone or testosterone

25 mg every second day. The nervous symptoms were less and erections occurred occasionally. In December 1936 he began to take testosterone propionate 25 mg every second day. In approximately two weeks he found himself sexually normal with great diminution in the sense of melancholy and irritability. With 25 mg doses of testosterone propionate, assay showed 10 units of urinary androgens, with 5 mg doses 18 units, with 10 mg doses 22 units and with 20 mg doses 80 units in twenty-four hours. Treatment was continued for sixteen months and during this period there was only the slightest possible suggestion of depression at times. Sexual potency has remained normal. At the date of writing, placebo substitution has been used for seven weeks without recurrence of symptoms.

#### CASTRATION

The symptoms of castration in the male may be completely relieved by injections of testosterone propionate if given in sufficient doses.

**CASE 8**—A man aged 64 presented himself in November 1936 complaining of extreme "nervousness, hot spells and loss of sexual power." In May 1934 he had complained to a surgeon of bilateral testicular pain. Bilateral orchidectomy was advised and the patient was led to believe implicitly that his potency would be unchanged and that no other symptoms would occur. Within a week hot flashes identical with those seen in the female

Fig 9—Data in case 8

climacteric began to appear together with a sense of oppression in the chest and head, melancholia and a sense of trembling. Within a month the ejaculate was less and in two months the libido was diminished and the potency lost. Since that time there had been a constant sense of excitement, tension and giddiness. Hot flashes increased to between twelve and thirty a day, and insomnia occurred. Prostatectomy was performed in September 1934, although apparently no symptoms of obstruction were present.

Physical examination revealed a well preserved man of 64. He appeared apprehensive and excited. As he sat in the examining room, he would suddenly become restless and marked redness of the face would appear, last for about a minute and be followed by profuse perspiration. The systolic blood pressure varied from 144 to 173 and the diastolic from 80 to 100.

There was evidence of mild arteriosclerosis. The fact that the prostate felt small was probably insignificant. The vibratory sense was diminished bilaterally below the knees, other sensations and the reflexes were normal. Blood counts, urea, calcium, phosphorus and blood protein values and Wassermann tests were normal. Urinalysis showed a little albumin and a few hyaline casts. The urea clearance was normal. The blood cholesterol content was 288 and 285 mg per hundred cubic centimeters. Dextrose tolerance following the ingestion of 100 mg of dextrose was as follows: fasting 102, one half hour 230, one hour 265, two hours 207, three hours 98 and four hours 68 mg. The sella turcica was normal to roentgen examination, the basal metabolic rate was  $\pm 0$  per cent. Friedman tests were done on five occasions, one reaction was

positive. Figure 9 indicates the levels of urinary androgens, the doses of testosterone propionate and, in a general way, the symptomatic improvement.

November 23 the daily administration of 5 mg of testosterone propionate was begun. For five days there was no change, after which a reduction in hot flashes was noted. No rise in urinary androgens was measured until December 18, in spite of increased doses. An erection occurred after one week of therapy. An acute infection of the respiratory tract caused a temporary increase in symptoms. By December 9 hot flashes were occurring only about four times daily. In February the mental unrest and melancholia were much diminished. Normal coitus was possible once or twice a week. There was a normal orgasm but no ejaculate. At the end of February, treatment was omitted for a week, toward the end of this time all symptoms were returning, and they continued to increase for several days after the resumption of 10 mg of testosterone propionate a day. By March sleep was normal and no sedation was necessary.

An increase in the dose produced an interesting effect, reported in July 23, 1937, by the patient's physician, Dr E C McDonald. "Mr S was given 25 mg of testosterone propionate June 17, and since that time he has received three ampules weekly. He has improved materially, both subjectively and objectively, with larger doses. Objectively, I am impressed by the fact that he is more alert mentally, in fact, I believe he is entirely without his former tendency to melancholia and complaints of nothing which is unusual for him. Subjectively, his libido is normal and he is able to perform sexual intercourse satisfactorily. The hot flashes gradually diminish from an average of four or five in twenty-four hours to a present level of not over two and usually one in the same length of time, these being milder and of shorter duration." He remained almost symptom free with 10 mg doses three times a week until about March 1, 1938, when impotence recurred. Between April 4 and May 4 injections of oil were given and care was taken not to place leading questions. The impotence persisted, but little complaint of general symptoms was made. May 4, 25 mg of testosterone propionate was given and between then and May 18 a total of 95 mg. May 6 polyuria was noted, and May 9 the first erection for two months occurred and the patient volunteered that the hot flashes had again become less severe and the "nerves steady." Subsequently, with doses of 10 mg three times weekly potency has been maintained.

#### SUMMARY

In cases of severe prepuberal hypogonadism, injections of testosterone propionate in the doses indicated have been followed by symptomatic and anatomic changes in approximately the following order. Penile erections occur promptly, and there is an increase in the pubic and axillary hair. The penis grows rather markedly and the scrotum less so, and the prostate growth appears to lag perceptibly in proportion. There has been no consistent evidence of increased testicular size, although the testes appeared to be larger after treatment in case 5. Nocturnal emissions occur and the quantity of semen increases. No diminution in sperm count or inhibition of sperm production has been obvious where sperms are present, though this may not be so in cases in which there is a normal number of spermatozoa before therapy. The larynx grows and the voice becomes lower. Facial acne appears and the beard grows. Epiphysal closure has not exceeded its expected normal rate in cases in which testosterone propionate alone was used and in one case has not increased in four years in spite of marked advance in puberty. No constant change in basal metabolism has been observed. In cases of functional hypogonadism in the adult this treatment has been followed by complete relief of nervous and sexual symptoms. In castrates, nervous and vasomotor symptoms and impotence can be abolished by sufficient doses.

#### ABSTRACT OF DISCUSSION

DR H L KRITSCHMFR, Chicago. I was interested in the results of the assay by the two methods that Dr McCullagh mentioned and to know just what takes place when these extracts are given. His results are very striking, and if this method can be used to stimulate the growth of the external genitalia it may have a definite field of usefulness. However, I think it might be desirable at this time to know what the effect of these drugs is on spermatogenesis. I believe that one may be justified in calling attention to the possible inherent dangers in some of these drugs. The point I wish to raise is that, while this drug has a certain field of usefulness, its indiscriminate use might possibly be attended by some undesirable consequences. Interesting in his experience is the fact that all the changes which occurred following the use of this drug were external, resulting in changes in the external genitalia, the growth of hair and the like. This subject, as Dr McCullagh stated, is still a debatable one. Koch called attention to the fact that this drug may have a deleterious effect on the spermatogenic function, and this it seems to me is an important point to bear in mind. I believe that the indiscriminate use of this drug should be discouraged until its effect on spermatogenesis has been definitely established. If, for example, this drug does have a deleterious effect on spermatogenesis, undesirable results may follow its use. I think it should be emphasized that this drug should be used under careful supervision in well selected cases. Some of the undesirable effects of the treatment of undescended testes with various endocrine preparations are beautifully illustrated in the exhibit of Drs Thompson and Heckel at the Scientific Assembly. I believe it would be most unfortunate if the indiscriminate use of this drug should be followed by interference with spermatogenesis.

DR GEORGE G REINLE, Oakland, Calif. This is a subject that we still do not know a great deal about, also there is danger in its being used promiscuously. Dr McCullagh's study has been gaged by the excretion of androgen. He has defined androgen as a chemical substance which can be found in human urine and which has pharmacologic properties similar to testicular extract. At present there is too little evidence for one to state definitely what cells in the body secrete the substances. That these substances may be found in the urine of a patient without testicular tissue has been exemplified by the case of castration cited in which these substances were found in the urine in quantities equal to those found in normal persons. Since early Biblical times it has been known that testicular functions are related to what are termed secondary sex characteristics. In spite of exhaustive research toward ascertaining the exact nature of this relationship, the problem is by no means solved. Today there is much dispute among certain workers regarding the function and secretion elaborated by such testicular cells as the cells of Leydig and of Sertoli. It has been shown quite convincingly that testosterone propionate given to young male chicks markedly increases the growth of the comb and markedly accelerates the time at which the young roosters exhibit definite signs of masculinity. Hamilton, in a recent talk to the Western Branch of the American Urological Association, showed a movie which exhibited evidence to the effect that testosterone propionate stimulated penile growth, pubic hair and erectile power in young persons with subnormal sex characteristics. Reports of studies with the injection of substances such as testosterone have been followed by the clinical use of this substance by many physicians for such complaints as impotence and cryptorchidism. The results in cryptorchidism are very difficult to evaluate because many retained testicles descend of their own accord as the patient grows older. As Dr McCullagh has pointed out, impotence cannot be considered evidence of hypogonadism. Although impotence may be due to the pathologic physiology of certain endocrine glands, it is often functional. Necessarily, any experimental work which is of value in increasing our knowledge of these subjects necessitates very diligent and thorough observation and a most careful analysis of the results found by the investigators. For these reasons I am particularly indebted to Dr McCullagh for his study of the treatment of testicular deficiency with testosterone propionate. He is to be complimented for his splendid work.

DR R V DAY, Los Angeles Testosterone is a potent drug. If one is to get physiologic results, one usually gets them fairly promptly. The cases that Dr McCullagh reported, of course, are examples of substitution therapy, and whether or not one obtains spermatogenesis or whether one produces erections or in some way relieves the impotence, I don't think matters very much, but there must be some metabolic phenomena. Perhaps they have something to do with the creatine anabolism. Certainly the patients experience a sense of well-being, that is in the cases of nervous exhaustion, asthenias and depressed energy states, and in those cases it is very useful if one does not expect too much from it. In artificial menopause in which there were severe symptoms there have been quite a number of patients who did not respond to estrogenic substances but did respond promptly to testosterone propionate. One of the advantages of the propionate salt is that it is slowly absorbed over a period of days so that larger doses may be given and need not be administered so often. I have sometimes given 100 mg a week. Its use is so recent that there is not yet enough clinical background for a thorough evaluation of its usefulness, and there will not be for perhaps the next ten or twenty years. It is very useful in early prostatism to relieve the irritability when infection has not yet occurred and the residual urine is of no great consequence. In such cases it does not make much difference what is done as regards its effect on the spermatogenic cells for the reason that in the case of these old men it is simply a replacement therapy. In the case of impotence one should use caution and not administer the drug over a considerable period, because in animals it has been demonstrated that degeneration of the spermatogenic cells in the tubules follows the intensive administration of testosterone if it has been continued too long.

DR L F HAWKINSON, Brainerd, Minn. After considerable experience with the use of androgen during the past three years, I can confirm what Dr McCullagh has said. It is becoming increasingly evident that the doses formerly used were inadequate. The original doses of 1 mg produced no results, 5 mg ampules produced some fairly good results. Since I have increased my doses to 25 mg two or more times a week my patients are responding with more regularity, and I want to call particular attention to the fact that Dr McCullagh used from 2,800 to 3,250 mg in treating these patients. Many so-called androgenic preparations in my experience have been of no value. Two years ago I tested nine so called androgenic preparations on white leghorn capons. Some of these products were labeled in capon units. It is noteworthy that the capon test proved seven of them to be worthless. Two preparations of testosterone propionate, made synthetically, were very potent. Concerning impotence, only about 20 per cent of my patients have obtained relief after injections of androgen. It is possible that I am using inadequate doses, this is suggested by Dr McCullagh's report. I have treated more than 100 patients with androgenic substance for prostatic hypertrophy. Although I am not prepared to report the results at this time, I have this much to say. Excluding two or three patients, there was a definite increase in well-being in these older men. They not only feel better but they are more active physically, more alert mentally and the nervous symptoms are usually ameliorated.

DR E PERRY McCULLAGH, Cleveland. I agree with Dr Kretschmer that caution should be employed in the use of these materials in patients in whom any spermatozoa are present or in whom spermatogenesis is normal. There are already some data which suggest that injected androgens do not harm spermatogenesis in the rat, whether or not this will be borne out for man remains to be established. It was shown by Dr Roy McCullagh in 1933 that in hypophysectomized rats the injection of urinary androgens extracted from male urine would maintain not only the prostate, vesicles and Cowper's glands but also the testes and spermatogenesis. At that time this work was not generally accepted. Later, however, it was adequately corroborated for testosterone propionate and other artificial androgens. This work was done in our own laboratory as well as by other workers, notably Nelson, who recently corroborated fully that these materials given in large enough quantities to animals having no pituitary glands to maintain their testes will not only do no damage but will actually maintain the spermatogenic elements. The exact mode of action of androgens under these

circumstances is not entirely clear. Cutuly favors the idea that scrotal maintenance may be of primary importance, but Nelson feels that the degree of maintenance of spermatogenesis and of the scrotum do not parallel each other and are probably not interdependent. Whether or not androgens will prove valuable clinically in producing spermatogenesis must remain for future work to determine. The treatment of impotence is difficult. Certain patients who have been impotent with no signs of hypogonadism and quite high levels of urinary androgens have been treated in spite of the high androgen levels, but with no improvement. On the other hand, certain patients with impotence and low levels of urinary androgens, which we believe are the result of poor general health have not been consistently improved even when urinary excretion has been raised to high levels. There is a group of patients with impotence, however, as I indicated, who have testicular deficiency as judged from the low level of urinary androgens, and in this group treatment with testosterone propionate brings about more consistent and more pronounced improvement.

## SULFANILAMIDE TREATMENT OF ERYSIPELAS

JOHN NELSON, M.D.  
HARVEY RINZLER, M.D.

NEW YORK

AND

M. P. KELSEY, M.D.

TEMPLE, TEXAS

Bellevue Hospital annually treats about 600 patients with erysipelas. Prior to 1937 the treatment of this disease was varied and not particularly effective. Erysipelas antitoxin, ultraviolet rays and local treatment of various kinds had all proved to be more or less ineffectual.

With the advent of sulfanilamide (prontylm and its related compound prontosil [the disodium salt of 4-sulfamidophenyl-2'-azo-7'-acetyl amino-1'-hydroxy-naphthalene-3,6'-disulfonic acid]) new hope was held for controlling this disease. Enough has been said and written about these drugs to preclude any detailed discussion of their action here. Their effect on hemolytic streptococci and other bacteria is by now well known.

TABLE 1—Patients Treated with Sulfanilamide

	Adult		Children	Average
	Male	Female		
Total cases treated	219	94	31	
Days of hospitalization	69	69	33	68
Days of fever	42	44	29	41
Deaths	4	1	4	
Mortality	1.8%	1.06%	12.9%	2.6%

Beginning Jan 1, 1937, all patients with erysipelas entering Bellevue Hospital were treated with sulfanilamide (prontylm and its derivative prontosil, prontylm in tablet form for oral use and prontosil for intramuscular injection). At first dosage was a problem, but in a short time a definite plan of treatment was formulated and has been adhered to in almost all cases. This is as follows:

1 For children up to 2 years of age two or three 5 gram (0.3 Gm) prontylm tablets are given every day and continued daily until the temperature reaches normal. The tablets are usually crushed and given with food or fluids.

2 For children from 2 to 5 years of age two 5 gram prontylm tablets are given three times a day (a total of 2 Gm) and discontinued forty-eight hours after the temperature has reached normal.

From the Third Surgical Division, Bellevue Hospital

3 For children from 6 to 12 years of age, three 5 gram tablets of prontosil are given three times a day (a total of 3 Gm) and continued daily until the temperature has been normal for forty-eight hours

4 Patients 12 years of age and over receive the following dosage

First twenty-four hours, 100 grams (65 Gm) of prontosil in divided doses

Second twenty-four hours, 80 grams (5 Gm) of prontosil in divided doses

Third twenty-four hours, 60 grams (4 Gm) of prontosil in divided doses

Fourth twenty-four hours, 40 grams (26 Gm) of prontosil in divided doses

Small doses may be continued for two or three days after the temperature has reached normal, and the dosage may be subject to change at any time, depending on the condition of the patient. When any gastric distress resulted from the use of the drug sodium bicarbonate in 10 gram (0.65 Gm) doses was given with each dose of prontosil with excellent results. Antipyretics and magnesium sulfate should not be given in conjunction with prontosil or prontosil.

Prontosil was used in only a few adult cases at the beginning of the study. It was used as a routine in infants too young to take tablets and in those adults who were unable to take oral treatment. One 5 cc ampule was given every four hours in adult cases. Infants received two 5 cc injections a day.

From January 1 to July 1, 1937, 344 patients with erysipelas were treated by this method. These patients all received the same nursing care, the same dressings (boric acid solution or cottonseed oil) and the same diet. Cathartics were used freely, magnesium sulfate being avoided. Of the 344 patients treated in this manner thirty-one were children under 12 years of age, 219 were men and ninety-four were women.

The average hospitalization was 69 days for adults and 55 days for children. The total average was 68 days for all patients treated. On the fifth day 13.6 per cent of the patients left the hospital.

TABLE 2—Patients Treated with Erysipelas Antitoxin

	Adults	Children
Cases treated	382	24
Days of hospitalization	11.1	12.8
Days of fever	6.8	10.0
Deaths	3.0	9
Mortality	9.2%	37.5%

TABLE 3—Patients Treated with Serum, Ultraviolet Rays, Roentgen Rays and Local Treatment with Dressings

	Adults		Children	Total
	Male	Female		
Total cases	2532	1484	437	4473
Average days stay	11.26	11.09	10.77	11.11
Deaths	197	93	86	376
Mortality	7.7%	6.3%	19.7%	8.4%

The average number of days for the temperature to reach normal was 4.1 days for men, 4.4 days for women and 2.9 days for children. The total average was 4.1 days for all patients treated, 44 per cent reached a normal temperature on the third day.

Complications of erysipelas in adults treated with prontosil were as follows: spread of the lesion, three cases, abscess formation either at the site of the lesion or elsewhere, five cases, pustular folliculitis, two cases, acute infectious arthritis, two cases, pneumonia, one case, and cardiac arrhythmia, one case.

Certain reactions were observed and attributed to the drug. Twenty-seven patients became cyanotic, but this was not considered a contraindication, and usual dosage was continued. Nausea and dizziness were observed frequently and vomiting occurred in four women. In one patient slight jaundice developed which disappeared four days after medication was discontinued. This patient was a chronic alcoholic addict with an enlarged liver. Another patient who entered with a history and preexisting diagnosis of alcoholism and cirrhosis of the liver died with jaundice and cholemia during the course of the erysipelas and sulfanilamide medication. Autopsy was not permitted. In these two cases we did not attribute the cause of the jaundice to sulfanilamide. One patient showed slight hematuria. After injections of prontosil seven children showed a pink tinge to the skin due to the color of the dye (prontosil).

There were five deaths of adults, or 1.5 per cent, and four of children, or 12.9 per cent.

In an evaluation, this series (table 1) may be compared with 406 cases treated with erysipelas antitoxin during the winter of 1935-1936 (table 2).

The summaries of these tables may be compared with the results of 4,473 cases from Jan. 1, 1930, to Jan. 1, 1937, in which various methods of treatment were utilized—serum, ultraviolet rays, x-rays and local treatment with dressings of different kinds (table 3).

## THE PRODUCTION OF BREAST GROWTH IN THE HUMAN FEMALE

BY THE LOCAL APPLICATION OF ESTROGENIC OINTMENT

CYRIL M. MACBRYDE, M.D.  
ST. LOUIS

The growth of the mammary glands in experimental animals has been extensively investigated and has been found to depend primarily on the estrogenic hormones.<sup>1</sup> Complete development in most mammals is dependent on the simultaneous action of estrogenic and corpus luteum hormones.<sup>2</sup> In spite of the excellent experimental background, I have been unable to find records of carefully controlled studies of human breast growth. I therefore performed studies on three women lacking mammary development and exhibiting signs of marked hypogonadism. In the first part of the study the hormones were administered by subcutaneous injection. I was able to demonstrate that, by the injection of from 150,000 to 350,000 international units of estrone or of estradiol benzoate per week, active mammary growth could be produced in patients who previously had no visible or palpable breast tissue. The results were recorded by frequent caliper measurements and photographs. During the treatment vaginal smears were changed from the inactive type to the active estrous state, there was enlargement of the

uterus, the vagina became deeper and the vaginal walls, previously thin, smooth and atrophic, became rugated, thick and soft. There was considerable psychic improvement, the outlook changing from that of abnormal, almost asexual individuals to one approximating that of normal women. This was especially true after artificial menstrual periods had been produced one or more times. Hypogonadal symptoms such as hot flashes and emotional instability were relieved, the basal metabolism rose, the appetite improved and there was considerable weight gain in these previously very thin patients.

Although I was also able to produce breast growth with injections of ketohydroxyestrin (estrone), estradiol benzoate was, unit for unit, much more effective.

Corpus luteum extract, 5 international units daily for a period of thirty days, when given alone produced no detectable change in the breasts. This is in accord with the experimental observations on animals of Turner,<sup>2</sup> Corner<sup>3</sup> and others. When, however, patients were given alternate daily injections of 1 international unit of progesterone and from 20,000 to 50,000 international units of estrone or of estradiol benzoate, breast growth was more rapid than that produced by the estrogenic hormones alone. The simultaneous use of the corpus luteum and estrogenic therapy definitely produced a much firmer breast growth, which was distinctly lobular to palpation, whereas the growth produced by the estrogenic hormones alone was smooth and the borders of the glandular tissue were difficult to define. Rapid regression in the size of the breasts followed the omission of the hormone injections, but the regression was less rapid when the combined therapy had been used.

So far as was possible by clinical criteria alone, I was thus able to confirm in the human female what had been suggested by previous studies on breast growth of experimental animals. Table 1 includes some of these results and the details of the studies are given in the case reports.

The second part of the investigation concerned the production of human breast growth by local injection

with estrogenic ointments. In the literature there is considerable evidence that estrogen is well absorbed through the skin and mucous membranes. The application of estrogens to the vaginal mucosa of animals has been demonstrated as more effective than injections in producing typical vaginal estrous changes.<sup>4</sup> The treatment of gonorrheal vaginitis in children, which is

based on the vaginal changes produced by estrogenic hormones, is best accomplished by the use of vaginal suppositories containing the active material.<sup>5</sup> Excellent results in the treatment of pruritus vulvae and kraurosis vulvae have been reported with local estrogenic therapy.<sup>6</sup> Certain dermatoses associated with hypogonadism are said to respond to local hormone treatment.<sup>7</sup> Kun<sup>8</sup> demonstrated that, in rats, percutaneous estrogen acts locally to improve cutaneous nutrition and stimulate hair growth. Burrows, Ito and Moore<sup>9</sup> have shown that enough estrogenic material can be absorbed through the intact skin of animals to elicit the characteristic general effects of the hormone, including estrus and breast growth. When an ointment containing estrogen is applied to the breast region of guinea pigs, nipple growth is produced, and, when the application is unilateral, nipple growth is greater on the treated side.<sup>10</sup> DeFremery<sup>11</sup> found that treatment of virgin goats with pituitary lactogenic hormone caused

the secretion of only a few drops of milk. If, however, the udder was first treated withunctions of estradiol benzoate there was considerable mammary development with changes of the preparturient type. Injections of lactogenic hormone at this stage induced lactation which was as abundant as that observed after parturition.

Loeser and Salmon<sup>12</sup> each found that the symptoms of castrate women could be relieved by percutaneous estrogenic therapy, and the latter demonstrated that a total cutaneous dose of from 160,000 to 300,000 i.u. units given over a period of from three to four weeks was necessary to produce a full estrogenic effect as determined by vaginal smears.

No studies have as yet appeared on the local effect of estrogen when applied directly to the human breast. I therefore omitted the injection therapy in my patients until the major part of the artificially produced growth had disappeared. An ointment of hydrous wool fat and petrolatum containing 5,000 international units per gram of estradiol or of estradiol benzoate was then applied directly to the breast region over a circular area approximately 10 cm in diameter with the nipple as the center. Each day 5 Gm., containing 25,000 international units, was applied, by the patient, to the breast region on one side rubbed in for five minutes, and allowed to remain on over night. The breast of the other side was used as a control and received the same amount of ointment base, without the estrogen, and the same amount of massage.

Definite breast growth of considerable degree was produced by the estrogenic substance absorbed through the skin directly into the breast tissue. Evidence of absorption of the estrogen into the systemic circulation was found in the change of the vaginal smears from the inactive type to the active estrous state, by change in the vaginal mucosa, by enlargement of the uterus, by relief of the patients' hypogonadal symptoms and by slight effects on the opposite breast.

I found little or no difference in the effectiveness of the estradiol and estradiol benzoate ointments.

The ointments, unit for unit, were more effective in producing breast growth than injections of estradiol benzoate or of ketohydroxyestrin (estrone). Ointments containing estrone were less effective, unit for unit, than those containing estradiol.

When breast growth was produced by injections of estrogenic material, there was diminishing effectiveness of the injected hormones. When the hormones were applied to the skin, however, there was a steady progressive growth.

Caliper measurements were made at frequent intervals and a photographic record was kept of the changes produced. The accompanying tables and photographs are abstracted from these records at salient points in the studies.<sup>13</sup>

#### REPORT OF CASES

**CASE 1**—An unmarried woman aged 24, first seen Dec. 3, 1935, complaining of lack of development of sex characteristics, nervous instability and hot flashes, had never menstruated. Many kinds of glandular treatment had been tried without success. Small doses of estrogen by injection had perhaps relieved slightly the subjective symptoms.

<sup>12</sup> Loeser, A. A. Resorption and Action of Follicular Hormone Rubbed Into the Skin. *J. Obst. & Gynaec. Brit. Emp.* 44: 710-714 (Aug.) 1937. Salmon, V. J. Skin Absorption of Dihydroxyestrin in Humans. *Proc. Soc. Exper. Biol. & Med.* 38: 481-484 (May) 1938.

<sup>13</sup> Estradiol benzoate (progynon B) corpus luteum hormone (proluton) and estrogenic ointments were supplied for these studies by Dr. Max Gilbert and Dr. Gregory Stragnell of the Schering Corporation. Estrone (aminotin) was supplied through Dr. J. A. Morrell of E. R. Squibb and Sons.

She was 5 feet 8¾ inches (175 cm) tall and very thin, weighing only 111 pounds (50 Kg). The arms and legs were long in proportion to the length of the trunk. From soles to symphysis pubis she measured 37¾ inches from symphysis pubis to vertex 31½ inches. The span with the arms outspread exceeded her height by 4½ inches. The face and manner were very feminine but there was no sign of breast tissue, the hips were narrow, the external genitalia and vagina were infantile and the uterus could not be palpated. Hair growth was normal except that it was very scanty in the pubic region. The skin was smooth, clear and delicate. Laboratory studies were within normal limits, except for the following: the basal metabolism was minus 15 per cent, the sugar tolerance curve was flat, roentgenograms showed that epiphyseal union had been delayed and had not yet occurred in the phalanges or at the distal end of the radius and ulna, and the vaginal smears were of the inactive or "castrate" type.

Substitution therapy with large doses of estrogenic hormone was advised. It was thought that the patient's ovaries were either absent or so atrophic that little or no effect could be expected with pituitary gonadotropic substance.

Treatment was started Jan. 8, 1936, with daily subcutaneous doses of 50,000 international units of estradiol benzoate. Within

Fig. 1 (case 1).—Breast growth produced after eight weeks application of ointment to the mammary region.

twelve hours after the first injection the patient noticed a clear vaginal secretion, never before present. There were also some lower abdominal pains which suggested uterine cramps. These results became more definite after the second injection. After six injections there was tenderness and enlargement of the nipples and areolae, and a darkening in color of the latter. At this time a disk of firm tissue about 4.5 cm in diameter was noted under each areola. The labia were very sensitive. After ten injections the breasts measured 4.7 cm in diameter and the uterus was palpable for the first time. The vaginal walls were turgid and rugated. February 1, after twenty-four daily injections, the breasts were 6.0 cm in diameter and 2.4 cm deep and the uterus was larger, although still much smaller than normal. At this time the dose was diminished to 50,000 international units three times weekly. The breast growth was maintained with this dose but did not increase during the next three weeks. All treatment was stopped for a control period of two weeks and there was rapid regression in the size of the breasts. Four days after cessation of treatment rather profuse vaginal bleeding occurred, lasting six days. The psychic effect of this was considerable. The patient said that now she had menstruated for the first time she felt like a normal woman. Treatment was resumed with 50,000 international units three times weekly and there was slow growth. Resumption of 50,000 international units daily brought a rapid increase in size of the breasts, nipples and areolae. During the next thirteen months the patient received from 30,000 to 350,000 international units a week. Definite breast regression occurred with less

than 100,000 international units a week. A maximum point of growth was attained with 350,000 international units a week. Continuation of this dosage accomplished no further increase in the breast size. Table 1 shows the breast measurements at various stages of the treatment. On estrogen therapy alone the patient gained weight from 111 to 130 pounds (50 to 59 Kg) and the basal metabolic rate rose from minus 15 to plus 4 per cent.

All treatment was omitted for a period of thirty days. The left breast only was then treated daily with 5 Gm of the ointment containing 25,000 international units of estradiol benzoate. The right breast was treated with the ointment base without the estrogen. The left breast increased in size while the right one showed little change. This was evident in ten days, and the unilateral treatment and growth continued for twenty-three days. Treatment of the right breast alone brought them to equal size, then bilateral treatment was given for twenty-eight days. The skin received a total dose of 50,000 international units daily. The rate of growth and total growth produced by this dose to the skin were slightly in excess of that produced by subcutaneous injections of 50,000 international units daily (table 2). Omission of the ointment treatment was followed by vaginal bleeding and rapid regression in breast size. The ointment treatment was then resumed with estradiol, the free hormone, as the active ingredient instead of the benzoate ester. Approximately the same results followed as with the estradiol benzoate ointment. Table 2 shows the breast measurements at various stages of the ointment treatment and figure 1 shows the patient before and after the treatment of the breast with estrogen injections.

**CASE 2**—An unmarried woman aged 24, first seen March 8, 1938 complained of lack of development of sex characteristics, anorexia, underweight and nervousness. She had never menstruated. With desiccated thyroid one-half grain (0.03 Gm) once daily and thelin 10,000 international units once weekly she had improved slightly. The basal metabolic rate had risen from minus 15 per cent to plus 1 and she had gained a little weight. There had never been any breast development, either before or after the injections.

She was 60 inches (152 cm) tall and weighed 89½ pounds (40.6 Kg). She had the general appearance of a girl of

injections) there were abdominal cramps, presumably uterine, and the vaginal smears showed active estrous changes. The nipples became erect and the areolae larger and darker by the end of the first week's treatment. The labia minora and majora enlarged, and after three weeks of treatment a small uterus was palpable by rectum. A disk of breast tissue was palpable at the end of the first week, and there was progressive breast growth at approximately the same rate as that obtained in

Fig 3 (case 3)—Breast growth produced after treatment only of right breast for twelve weeks with ointment.

case 1. When the estrogen injections were omitted, vaginal bleeding occurred for the first time in the patient's life and lasted four days. Breast growth regressed on omission of therapy but was resumed when injections were resumed. After three months of treatment the breast diameters were approximately 10.5 by 8.0 cm, their depths 4.5 cm, the areolae measured 2.8 cm. Treatment with 50,000 international units daily except Sundays (300,000 international units a week) was continued and no further increase in breast size occurred. Treatment was then omitted for two weeks and the breasts became smaller, the diameters being approximately 6.1 by 5.8 cm and depths 2.5 cm.

Fig 2 (case 2)—Breast growth produced after three and one half months' use of estrogenic ointment.

approximately 12 years. The manner was entirely feminine, the hair and skin were normal. There was no visible or palpable breast tissue. The areolae were very small. Their color was that of the surrounding skin. The very small nipples were inverted. The external genitalia and vagina were infantile and the uterus was impalpable by rectal examination. Vaginal smears were of the inactive type.

Treatment was started with 100,000 international units of estradiol benzoate subcutaneously three times weekly. The first notable effect was the appearance of a vaginal secretion at the end of forty-eight hours. After ninety-six hours (two

Estradiol benzoate ointment was then applied to the right breast only, and the left breast was used as a control, receiving the ointment base without the estrogen. The right breast definitely increased in size during a two weeks' period, while the left gland showed little change. The ointment was changed to estradiol, the unesterified form, and growth continued at the same rate. After nine weeks' treatment the right breast measured 9.8 by 9.0 cm, depth 4.4 cm, areolae 2.5 cm. The left breast measured 7.1 by 7.0 cm, depth 3.5 cm, areola 2.2 cm. The left breast was then brought up to the size of the right by treating it alone for three weeks. Then both breasts were treated, each receiving 25,000 international units of the estradiol ointment a total of 50,000 international units daily to the skin. After five weeks of the bilateral treatment

each breast measured approximately 10.4 by 10.3 cm, depth 5.1 cm, areola 2.7 cm and the areolae were large and dark, nipples large and erect. Figure 2 shows this patient before and after the ointment therapy.

**CASE 3**—A married woman aged 28 complained of nervousness long periods of amenorrhea and breast atrophy. Her breasts and menses had been approximately normal until after the birth of a child. Thereafter her periods were scanty, were of very short duration, and occurred at intervals of from six to twelve weeks. Both breasts had become very small but the right one had atrophied to such an extent that it was only half the size of the left. Vaginal smears showed variations from slight to moderate estrous activity. The vagina was normal, the uterus small.

Ketohydroxyestram injections were started in doses of 30,000 international units three times weekly. Slight breast growth on both sides resulted, but after six weeks of this therapy a level was reached beyond which no further growth was evident. The right breast remained much smaller than the left. Ketohydroxyestram 50,000 international units three times a week was given and there was some increase in breast size with the larger dosage. All treatment was then omitted. It was thought that this patient whose right breast was considerably smaller than the left, presented an excellent opportunity for study of the local ointment effect. The breasts became much smaller after the injections were discontinued for twenty-six days.

Beginning July 27, 1938, 5 Gm of the estradiol ointment containing 25,000 international units was applied to the right breast daily. The left breast received the control treatment with hydrous wool fat-petroleum ointment base without the estrogen. There was a gradual increase in the measurements of the right breast until after twelve weeks treatment. October 19 the right breast actually was larger than the left (table 3 fig 3). Systemic absorption was manifested by relief of nervousness, marked increase in vaginal secretion, enlargement of the uterus, the constant presence of vaginal smears showing marked estrous activity, and some increase in the size of the left breast.

#### COMMENT

These studies demonstrate that estrogens can be absorbed through the skin of the human female directly into the breast tissue and by this route can produce their characteristic stimulation of mammary growth. It is definitely not recommended that this method be adopted in general practice until further studies can be done and the limitations and possible dangers of the cutaneous application of concentrated estrogens can be defined.

From the strictly histogenic standpoint, the mammary glands should be considered as appendages of the skin and may be regarded as modified sweat glands. The glandular elements of the breasts are derived from the ectoderm. When local action of administered hormones is desired, it seems as logical to use the percutaneous treatment to the breasts as to use estrogenic substances on the vulva and in the vagina to relieve kraurosis or vaginitis. For the many patients in whom only a general effect is desired, the method of choice will no doubt continue to be subcutaneous or intramuscular injection. As we learn more about the local action of hormones, however, it may be necessary to choose between routes which involve the entrance of hormones into the general circulation and those which depend on local action on organs or tissues accessible from the exterior.

#### CONCLUSIONS

Estrogenic hormones applied to the skin of the mammary region of the human female will act locally to produce breast growth. Systemic effects such as are obtained by the injection of large doses of estrogen were produced by percutaneous absorption of the administered hormones.

## Clinical Notes, Suggestions and New Instruments

### GIOMUS TUMOR (GLOMANGIOMA)

CLAREMONT PAUL DOANE, M.D. FRESNO CALIF

Glomus tumors of the digits of the upper extremities have been recognized since they were first described by Masson<sup>1</sup> and Barre and Masson<sup>2</sup> in the French literature in 1924. These tumors are comparatively rare and are probably frequently overlooked clinically. Bailey<sup>3</sup> reports that in the eleven years following Masson's description of the tumor only fifty-eight instances of glomus tumor were recorded. If they are not overlooked, their exact nature may not be clear. It is my purpose in this report to call attention to them briefly and to record a typical case.

Glomus tumors may occur anywhere over the cutaneous surface of the body, but they occur most frequently in the extremities,<sup>3</sup> and especially in the digits of the upper extremities. The histologic structure is now well known, and the histogenesis of the glomus tumor was readily established.<sup>4</sup> Those interested in the histology of the tumors are referred to Bailey's<sup>3</sup> detailed report.

Fig 1—Section from specimen obtained in case reported. Note irregular vascular lumens surrounded by glomus cells. The vessels are separated from one another by homogeneous material. Reduced from a photomicrograph under low power.

The tumor is solitary and small and is a rose or purplish blue. It varies in diameter from 4 mm to 10 mm.<sup>5</sup> The tumor may be raised so that it is easily seen, or it may extend into the subcutaneous tissues and be neither visible nor palpable.<sup>6</sup> These tumors are exquisitely tender and pressure on one produces lancinating pain of a severe variety. External cold may produce paroxysms of pain. It is described as a burning stabbing pain, which radiates up the extremity (if the tumor occurs in a digit). Cases have been reported in which these

painful tumors have been present for as long as thirty years Kolodny<sup>6</sup> in a recent report calls attention to a case in which sweating of the finger on irritation of the nodule was noticed. He feels that this phenomenon adds to our knowledge concerning the physiology of sweating.

In four of Adair's<sup>7</sup> cases the tumor was associated with the bed of the nail. Masson's patients had subungual tumors. My case is that of a subungual tumor.

#### REPORT OF CASE

Mrs. D. R. C., aged 31, white housewife, was referred to me by Dr. R. J. van Wagenen March 8, 1938. For years she had suffered from pain in the tip of the middle finger of her

Fig. 2—Showing the numerous irregular vessels and clusters of glomus cells. Reduced from a photomicrograph under high power.

left hand. She could not remember when she first began to have this pain, but she associated its onset with a severe contusion of the ring finger of the same hand when she was about 10 years old. The middle finger was not involved in this accident. For a year or two after she first began to notice it the pain gradually became worse and the tip of her finger became more sensitive. During the next eighteen years there was little change in the character of the pain or of the tenderness. She was observed occasionally by various physicians who offered no treatment that gave her relief.

About two years ago she began to notice an increase in the tenderness and in the amount of pain that she experienced. Whereas formerly radiating pain was not severe it now became quite marked. At times pain, which originated in the tip of her finger, radiated well up into the arm and was of an intense nature. Thinking she was suffering from some inflammatory lesion, and on the advice of a physician, she had roentgenograms made of the painful digit. The roentgenograms were reported negative. About this time amputation of the finger was advised as being the only solution for her problem.

For two years she postponed doing anything about the proposed treatment, hoping that her finger would eventually cease to be painful. Recently, however, the pain became so bad that 'all (her) fingers ache' and she was becoming desperate enough to submit to any treatment which could offer her relief.

Examination of the finger revealed that it looked normal, apparently no different from any of the other fingers. The patient localized the source of the pain in a small area beneath the nail, at the margin of the lunula. She insisted that she could notice a "bluish" discoloration at the point which, when touched, gave rise to the pain. When the finger was observed in direct sunlight an area could be seen which seemed to have a slightly deeper color than the rest of the nail bed. The difference in shade was so slight as to make one wonder whether it was actually present. Pressure over this area gave rise to pain which was almost intolerable. No other areas of abnormal sensation were found on this or any of the other fingers.

A diagnosis of subungual glomangioma was made, and removal was advised. A tourniquet was applied, and under local anesthesia the nail was removed. The matrix was incised over the point of tenderness noted previously. When the matrix was spread a mass of what appeared to be fat tissue protruded. A small soft encapsulated tumor about 5 mm in diameter was removed. The tumor resembled a small lipoma. The bed of the tumor was smooth and extended inward to the terminal phalanx. Hemorrhage from the tumor bed after release of the tourniquet, was quite profuse but was readily controlled by the application of pressure for a few minutes.

The specimen obtained was submitted for pathologic examination and the pathologist's report confirmed the clinical diagnosis of glomangioma.

Convalescence was uneventful. The patient experienced none of the former pain. Two months after surgery the nail had grown normally and was nearly as long as the other nails. There was no tenderness, and the patient was completely free from pain.

#### SUMMARY

Glomangiomas, though rare, are worthy of attention because when they do occur they are extremely painful and quite disabling. As in the case presented, the true nature of the condition may be overlooked clinically.

#### CONGENITAL ABSENCE OF BONES OF THE LOWER LIMB

JAMES A. BRUSSEL, M.D., BRENTWOOD, ILLINOIS

While anomalous conditions present at birth of the bones of the leg and foreleg are not rare, they are sufficiently unusual to be reported and should be recorded to maintain accurate statistics in these cases. Unfortunately the figures of the early years, particularly those prior to use of the roentgenogram, have been inaccurate chiefly because of the paucity of clinical means to ascertain definite pathologic conditions and, as a result, some of these observations have since been revised. For example in 1846 Proudfoot (quoted by Cotton and Clute)

Fig. 1—Patient in supine position after narcotization administered because she would not cooperate in conscious state. The deformed limb appears bent at the knee but is perfectly straight, outstretched and parallel to the normal left leg.

reported a case of congenital absence of the fibula in which he stated that 'the tibia of the same limb seemed to have a compound fracture at the middle.'

Freund<sup>1</sup> regards the figures of Nilsson<sup>2</sup> as the most conservative in the review of congenital absence of the femur.

From the Female Reception Service of the Pilgrim State Hospital.  
1. Freund, Ernst. Congenital Defects of Femur, Fibula and Tibia. Arch. Surg. 23: 349-391 (Sept.) 1936.  
2. Nilsson, H. Ueber den kongenitalen Femurdefekt. Arch. f. Orthop. 26: 138, 1923.

The latter collected seventy two cases up to 1928 and added ten of his own. Since then the literature has disclosed twenty-one additional cases,<sup>3</sup> which with the one about to be reported represent a total of 104 cases. This number is to be regarded as small for a period of almost a century. Dankmeijer<sup>1</sup> uncovered seventy-seven cases of congenital absence of the tibia of which twenty one were bilateral, up to 1935 and added one case of his own. Since then sixteen others have appeared,<sup>6</sup> bringing the total up to ninety-four. For the fibula Nutt<sup>6</sup> reduced Handek's figure to ninety-eight and since then sixteen more have been added<sup>8</sup> bringing the total to 114.

To recapitulate, congenital absence of the bones of the lower limb reveals the following totals: (a) femur 104, (b) tibia ninety four and (c) fibula 114.

The etiology of the absence of a bone or bones at birth has not been definitely established though several interesting ideas have been suggested. Most writers have discarded the primitive fin theory<sup>7</sup> advanced by Gegenbauer, and lean to the amniotic theory as probably more correct. Cotton and Chute have explained the lesion on this basis, as have Tubby, Taylor and others. As early as 1910, Whitman<sup>9</sup> felt that the deformity is associated with absence of bone due either to an original defect in the germ or to interference with its development. However he did believe that amniotic adhesions might be one

of the predisposing causes. Reimer states that the first cause of the condition is due to external pressure on the embryo from the amniotic bands, and the second a faulty development of the embryonic tissue and cartilage. More recently, Ollerenshaw<sup>10</sup> has written that the predominant cause is undoubtedly a cessation of growth in one or the other set of embryonic cells at a period he places between the fourth and the sixth week of fetal life.

The psychologic implication of such a condition becomes quite apparent especially when a frank psychosis develops in a person born with this defect which might, on first glance, be attributed to the birth defect. The report of such a case follows.

**History**—H. G. a white woman aged 34, married, was native born of Irish descent.

The family history was negative for mental or nervous disorders for at least two generations.

The patient was the ninth child in a family of eleven, born in Pennsylvania July 14 1903. The congenital absence of the right femur was noted at birth but never created a great disability since the patient learned to get about quite well with a

Fig. 2.—Appearance of the hips. The right limb shows rudimentary remains of an immature lower end of the femur.

crutch nor did she ever openly express any inferiority because of this infirmity. She completed two years of high school education by the time she was 15 and following this worked as a typist and telephone operator without experiencing any difficulty. Otherwise her medical and surgical history is negative. She married at the age of 24 she has one child but no other pregnancies. She is described as having been friendly, sociable, alert, active and particularly fond of music. While her husband states that marital life has been quite satisfactory, a sister of the patient insists that this is not true and that many quarrels have taken place at the home and on one occasion the husband left the patient.

**Psychosis**—The patient's sister feels that the psychosis is the culmination of a long series of marital difficulties, while the husband associates it with the death of the patient's mother in November 1936. Shortly after this death the patient began to pray a great deal showed little interest in what went on about her and finally began to refuse food. She was not very communicative but finally expressed a fear that her husband and others were trying to poison her. Her actions became increasingly strange and bizarre. She would open doors and peer out as if looking for some one or something but never expressed her thoughts freely in words. She finally became mute and withdrawn, she would lie on her bed totally inactive but would eat if food was left in her room and she was entirely alone. Jan. 22 1937, she was admitted to the psychopathic ward of Bellevue Hospital, where physical examination corroborated the foregoing observations. Mentally she was mute, negativistic and passively resistive.

She was admitted to Pilgrim State Hospital January 29 on a regular order of commitment. During the admission routine she was entirely mute. Physical examination revealed malnutrition, an asthenic habitus and absence of the right femur, subsequently corroborated by roentgenographic studies. The roentgenograms (figs 2 and 3) show that the head of the tibia is attached to a rudimentary union of approximately the lower eighth of what would have been a femur, but even the lower end of this femur shows poorly demarked condylar processes. Figure 1 was taken of the patient in the supine position after she had been narcotized with sodium amytal, since she would not cooperate for a photograph in her conscious state. The deformed leg appears as a bent knee, but this is not the fact. The leg is in its normal outstretched position and parallel to the normal leg. There were retroversion of the uterus and lacerations of the cervix. The Wassermann reaction of the

Fig 3—Appearance of right hip showing knee joint in right pelvis

blood and routine laboratory examinations were all negative. Mentally the patient was passively resistive, kept her eyes closed, was entirely mute and showed no emotional display of any sort. She lay on the examining bed with a blank expression on her face, occasionally relieved by a weak smile. The musculature was relaxed and atonic. She has subsequently remained essentially the same though sometimes she is observed laughing to herself as though in response to hallucinatory experiences. She is completely withdrawn from her environment showing little spontaneous interest or activity but seemingly preoccupied

with her fantasies or hallucinations. Her condition was diagnosed as schizophrenia (dementia praecox), catatonic type.

Regarding the psychologic implications in this case adherents of Adler's theory of organic defect will find admirable substantiation of their belief, as is not unusual in any functional condition such as a catatonic state in which muscular and postural phenomena are noted. However, opponents to this idea will claim that the patient adjusted more than satisfactorily to the demands of society despite this defect and that only with the advent of an unhappy marriage did the psychosis develop, the unfavorable union being interpreted by the ego as a threat to its integrity with the need for withdrawal from reality for its preservation. Of course adlerians may argue that the patient felt that her failure at marriage was due to her deformity appearing as a disagreeable entity to her husband. While such arguments pro and con could continue ad infinitum it is not my purpose in this paper to favor one side or the other. Suffice it to say that in this case the prognosis is definitely poor. Hypoglycemic shock therapy was not attempted because, at the time, insulin and/or metrazol therapy had not yet been employed in this country with the widespread use it is now accorded.

**The Length of Life**—In the sixteenth century the average length of life in western Europe is said to have been nineteen years, in the seventeenth century, twenty-five years, in the eighteenth century, thirty-two years. In the nineteenth century in this country life averaged about forty years, but by the end of the first quarter of the twentieth century the life expectancy at birth had increased to about fifty-seven years for boys and to about sixty years for girls.—Diehl, Harold S. *Healthful Living*, New York Whittlesey House 1935

### THE OPHTHALMOSCOPIC SIGNS OF CONSTITUTIONAL DISEASE

A SUMMARY OF THE SALIENT POINTS MADE IN A LANTERN SLIDE DEMONSTRATION OF COLOR PHOTOGRAPHS OF LIVING HUMAN EYES

CLINICAL LECTURE AT SAN FRANCISCO SESSION

ARTHUR J. BEDELL, M.D.

ALBANY, N. Y.

The background of the eye is the stage on which many of the tragedies of life are enacted. By careful, repeated examination, early changes can be detected and steps taken to eradicate or diminish the ravages of destructive forces.

By the use of a simple ophthalmoscope and the expenditure of a little time and concentration every physician will be able to recognize the fundus signs of the major vascular changes and the alterations from diabetes, hypertension, nephritis, syphilis, tuberculosis, intracranial pressure and optic nerve inflammations.

Obviously, before any one attempts to diagnose fundus lesions he must be well grounded in the great number of physiologic variations. For that reason, a careful analysis must be made of every case, and a detailed, orderly inspection should be followed by a judicial review of the possibilities before one arrives at a prognosis.

The normal disk may be comparatively small or rather large. It is paler than the surrounding fundus and may be outlined with a white or pigmented arc or ring. In the center of the disk there is a depression which varies much in diameter and depth, this, the central excavation, is an important landmark.

The retinal vessels course over the disk and the entire visible fundus. The arteries are easily distinguished from the veins by their lighter color and rounder form.

The number of branches and the method of distribution from straight to very tortuous are never the same, so that each fundus is a distinct entity. The dark region of the macula is usually two disk diameters beyond the temporal edge of the disk and slightly below the horizontal level. Overlying its deepest part is a bright spot, to which the name foveal reflex has been given. In

reality the shining dot comes from the vitreous and not the retina. The color of the background may be a uniform pink or almost white, through which the choroidal channels are easily seen and distinguished from the regularly arranged pattern of the retinal tree, or it may be mottled with dark and light markings.

Fig 1—A normal fundus. The bright figure eight is the image of the carbon arc which supplies the illumination. The pale oval center is the nerve head from which the vessels diverge. The dark region to the left is the macula. The veins are wide and darker than the arteries.

Read in the General Scientific Meetings at the Eighty-Ninth Annual Session of the American Medical Association, San Francisco, June 13, 1938.

During the course of embryologic life certain anomalies may develop. The border of the nerve head may fade into a pale arc or a depressed crescent, or, in the extreme case, the end of the optic nerve may lie in a cup of undeveloped choroid, the macular region may be an oval white hole, a coloboma, or a large portion of the choroid may be absent in the lower segment of the fundus. The sheath of Schwann may pass beyond the lamina cribrosa and appear as glistening white, small

The macula is dark red. After several days the pallor lessens, but the blindness persists. Eventually, if it was caused by an embolus one or more sclerotic patches form in the wall of the artery or arteries.

When the closure follows a chronic disease of the blood vessels the terminal shutting off of circulation produces a white zone similar to but sometimes less intense than that found in embolism. Retinal hemorrhages and white exudates are probably always present

Fig 2—Embolism of the central retinal artery, right eye of a man aged 51 a few hours after sudden and complete blindness. white edema, pink nerve head and red macula.

Fig 3—Thrombosis, endarteritis obliterans of the central retinal vein, right eye of a man aged 48. blood distributed over and between the arcuate nerve fibers of the retina.

Fig 4—Arteriosclerosis, right eye of a man aged 51. narrow arteries with white sclerotic patches and visible walls.

or large masses about the disk or in remote portions of the fundus. The teased, shredded, fibrillated structure is diagnostic and should never be confused with exudate. Bright glistening yellowish dots lying beneath the retinal vessels are called druse. They never interfere with vision and may be isolated or confluent even to the extent of forming a thick, dappled sheet.

When sufficiently trained every physician should be able to recognize pathologic signs. The correct interpretation of all of them is a life study, and yet every one can become proficient enough to recognize gross

Occlusion of an isolated artery branch may produce a localized whiteness corresponding to the region nourished by it. An oval central zone may receive its blood supply through the chorioretinal system, and in that way central vision is retained even when the major retinal artery is imperforate.

In sharp contrast to a closed artery is a plugged vein. When the central retinal vein is thrombosed the distal branches become immensely engorged, appearing as tortuous red loops which dip into the swollen retina and are lost to view. There are many hemorrhages and

Fig 5—Hypertensive retinitis, early stage, left eye of a man aged 50. blood pressure 224/108. increased artery reflex, edema of retina, gray white cloudy patches.

Fig 6—Hypertensive retinitis of twelve years duration, left eye of a man aged 62. blood pressure 220/160. artery wall reflex, increased veins, indented, many hemorrhages in the retina.

Fig 7—Hypertensive retinitis, right eye of a man aged 59 fourteen months before death. widespread retinal edema, irregular caliber arteries, many fresh and old retinal hemorrhages. blood pressure 182/100.

changes and by constant daily application steadily improve his diagnostic capacity.

The easiest way to begin the study of fundus diseases is by examination of the changes in the retinal blood vessels.

Sudden occlusion of the central retinal artery presents a characteristic appearance, the back of the fundus turns white. This is seen a few minutes after the patient complains of sudden blindness, which comes on unaccompanied by pain or congestion of the eyeball

often white exudate flecks. Thin linear hemorrhages follow the course of the arcuately distributed retinal fibers. Closure of a branch may, when the blood seeps down and covers the macula, materially interfere with vision. The blood may absorb, leaving little or much residual damage, or there may be a sudden, sharp pain with congestion of the eyeball, a dilated pupil and an increase in intra-ocular tension, hemorrhagic glaucoma, which does not respond to treatment and almost invariably leads to enucleation.

Gross retinal arteriosclerosis should be a common disease of the fundus, but actually it does not often reach the great white atherosclerotic stage. White patches in the artery may be observed through their advancing stages until occasionally the walls become white cords similar to the pipestem radials of far advanced general arteriosclerosis. Care must be taken not to confuse the increased visibility of vessels on or

While these fundus manifestations pass through their cycle (and incidentally, this may take twenty or more years) the vessels have undergone the changes which make it practically impossible to distinguish sharply arteriosclerosis from hypertension. Early signs of both are vein displacement, vein indentation, sometimes a dilatation of the vein between the artery constrictions, an increasing visibility of the artery wall and a coppery

Fig. 8—Senile macular degeneration retinitis circinata type left eye of a woman aged 72. A crown of whitish retinal exudates surrounds a gray edematous degenerating macular region.

Fig. 9—Malignant hypertension nephrosclerosis left eye of a man aged 44 who had had hypertension for years and who died of uremia four weeks after photograph was taken. Extreme artery changes with sclerosis, irregular caliber and stiff walls indenting full veins, retinal edema and hemorrhages, new vessels on disk.

Fig. 10—Nephritic neuroretinitis left eye of a woman aged 23, fourteen months before death. Great hemorrhages on the sides of the swollen nerve head, waxy exudate with suggestion of a star.

close to the disk as an indication of arteriosclerosis, for in this region the vessel sheath is often visible and yet devoid of pathologic significance. In syphilis white artery walls are not uncommon.

Arteriosclerosis and retinal hypertension are so often combined that the association deserves careful attention because of the increasing prominence it is receiving and will continue to merit. If the presence of edema is considered a requisite of hypertensive retinitis, then the characteristics of the disease can be defined as edema, greatest where the retina is thickest, usually the nasal

reflex, which later becomes a silvery gray and still later a white streak, or, and clinically this is easily demonstrable, the entire artery tree straightens and contracts or the reverse happens and the arteries become more tortuous.

To complicate the picture of arteriosclerosis and hypertension further, exudates appear. Some are irregularly placed yellowish ones, others form a circle, and when the macula is included within its boundaries it is called retinitis circinata. A similar exudate crown may be remote from the macula, three distinct rings

Fig. 11—Renal retinitis right eye of a man aged 33 who had had nephritis for three years and who died in coma three months later. Gray retina, macular star exudate.

Fig. 12—Retinitis in diabetes left eye of a woman aged 62, blood sugar content 157 mg. Extensive glistening yellow white exudates, many retinal hemorrhages.

Fig. 13—Retinitis in diabetes, the same case as that represented in figure 12. The photograph having been taken six months later, extension of retinal change even when the diabetes was seemingly under control.

side of the disk, and a few or many hemorrhages, combined with whitish, gray, soft masses usually near the major vessels. These signs will ultimately become more dominant with more hemorrhages, more and larger snowbank masses and greater nerve head swelling. If the patient does not die at this time, the edema, the hemorrhages and the exudates often subside until only a mere trace remains. Then or shortly thereafter dark chocolate brown spots appear near the posterior pole. These are of serious import and are one of the more certain signs of impending dissolution.
